An explosion of such suddenness and violence as to do damage twenty, thirty or even forty miles away as reported could not conceivably have been essentially a gas explosion. In the first place, it is very doubtful whether sufficient quantities of combustible or explosive gas existed at the plant to account for even the damage within the city of Oppau itself. And the characteristics of the explosion, if properly described in the press, are not those which result from the rupture of high-pressure containers. It seems evident, therefore, that it must have been some form of solid material which could be detonated that was the cause of the principal

damage done. Of course in any such case the initial cause of trouble and to what extent the principal cause was a secondary explosion can be disclosed only by careful investigation, and perhaps not even then.

It is known that this plant has been for some time experimenting with mixtures of ammonium nitrate and sulphate for fertilizer use with the idea of developing a material of highest agricultural value that would also be free from the objection of deliquescence. Accumulations of this material or of ammonium nitrate may well have caused the major explosion and the extensive damage. Of course there are also possibilities of nitrated organic compounds of high explosibility that may have been under investigation as intermediates for dye manufacture. It is almost useless to speculate regarding these details, for even the best informed specialists in this country who have tried to keep in touch with the work at Oppau are unwilling to venture more definite opinion than that expressed above.

The Conference On Unemployment

SPECULATION is rife as to what may be accomplished by the President's conference on unemployment now in session in Washington. Granted that there is urgent reason for focusing the best thought of the country on the problem, what practical consequences can be expected? For the immediate relief of unemployment, which is the critical factor, it seems likely that little can be accomplished. But the conference will be worth the time and energy expended if it clearly formulates broad policies that will prove a remedy or at least a palliative for widespread unemployment in the future. The program of the conference has three phases: First, the presentation of recent reliable statistics of unemployment; second, the consideration of possible immediate remedies, and third, consideration of economic and industrial processes that will prove to be long-time remedies. As in the case of President WILSON'S First Industrial Conference, useful and practical results depend largely on guidance that will keep the conference from being sidetracked on non-essential issues such as controversies between employer and employee. Under Mr. HOOVER'S direction we may confidently expect the conference to avoid any such fiasco. The fundamental factors brought out will be recorded in the technical and business press of the country to the exclusion of more spectacular but less essential matters of controversy that may be featured by the newspapers.

Denying a Pernicious Rumor

UNFOUNDED rumor has been circulated during the last two weeks to the effect that cases of infantile paralysis exist in the vicinity of Lake Placid, New York, where the American Electrochemical Society will hold its regular fall meeting September 29 and 30 and October 1. We are glad to be able authoritatively and unqualifiedly to deny these rumors. Members of the Lake Placid Club who are also members of the American Electrochemical Society have the assurance of the club officials that there is no foundation for the rumor, and we have also made an investigation which satisfies us that conditions at the Lake Placid Club are normal and that there is no cause for alarm. Members of the Society and readers of CHEM. & MET. can confidently deny the rumor should it persist.

Readers' Views and Comments

The Slip Interference Theory

To the Editor of Chemical & Metallurgical Engineering

SIR:—I would like to congratulate the authors of the Slip Interference Theory on the excellent work they have done in examining the problem of hardening of metals, not only from the point of view of the usual hypo-eutectoid steel, but taking into consideration the other alloys as well. I especially appreciate the authors' reference to duralumin, one of the alloys of the future, and the marked tendency of the paper to find a general solution of the hardening problem.

Examination of the summary (clauses 1 to 8) as well as the text finds abundant proof as to the interest the authors have shown in the crystallography of alloys. One may follow also with great interest the authors' argument that "every known method of hardening metals can be referred to the principle of slip interferences" and to the action of small "key-particles."

Further, the writer would like to emphasize that some of the facts derived from the study of damascene steel may be interpreted as supporting the authors' general views. So, for instance, the heat-treatment of damascene blades¹ could be more easily explained by taking into consideration not only the hardening phenomena as they are usually interpreted in hypo-eutectoid steels but the "keying" action of the small cementite particles as well. Hypo-eutectoid steel usually served as a point of departure for the theories of hardening of steel. In view of the absence of free cementite in these steels the influence of cementite particles was never sufficiently appreciated. Even the "carbon" theories sought for a new modification of carbon or of carbide and not for the possible rôle of the particles of the existing carbide in the hardened metal.

When studying damascene steel the writer came across the fact that such theories as would explain sufficiently well the hardening of hypo-eutectoid steel seemed unable to account for the heat-treatment of damascene blades or for their certain "high-speed hardness." He therefore sought for explanation elsewhere, and naturally enough was attracted by the idea that the presence of a large number of highly spheroidized cementite globules might furnish the necessary explanation. He must confess, however, that up to now he admits the hardening effect of cementite particles only to a certain degree and is rather reluctant to overestimate such influence. So, for instance, the properties of martensite seem to me to be best explained by its structure, which, "crystallographically" speaking, is characterized by Widmanstätten figures.² These figures result from the octahedral crystallization of steel and show that the elemental octahedra were deformed parallel to the four surfaces of the octahedron.

In austenite we have the gamma iron, and the iron carbide, cementite, is evenly dissolved in that iron. By rapid cooling it is possible to prevent the segregation of the carbide, and in martensite, where iron has passed

from the non-magnetic gamma to the magnetic alpha state, cementite remains in a suspended form, as if in solution.³ The sudden change of volume from gamma to alpha iron causes severe internal stresses which manifest themselves by deforming every elemental octahedron parallel to its four faces. The hardness of martensite results very likely from these internal deformations. I am therefore quite in agreement with the authors that martensite is alpha iron; where we differ is, first, that I consider martensite as a pseudo solution not of carbon, but of cementite in alpha iron; and further that not only the fineness of grain but chiefly the "Widmanstätten structure" of the deformed elemental octahedra is responsible for the hardness.

I do not think that colloidal suspended particles of cementite may act as keys in martensite. On the other hand, I join the authors in their appreciation of Captain Grard's curves. I am quite in agreement, therefore, with the authors' idea that the first "increase" in hardness after tempering is due to the "key" action of the segregating cementite.

The only reservation which the writer would like to make is that in this instance, as in other instances, the "key" action is responsible for a comparatively small increase in hardness and that there is a difference in scale between the "key" hardness and the "quenching" hardness.

While still believing that carbon in solid iron is present not as such but as iron carbide (or cementite),⁴ nevertheless I do not think that if the authors were to consider austenite from that point of view it would in any way change the main deductions of their so brilliantly exposed theory.

COLONEL NICKOLAS T. BELAIEW.

Athletics and Chemistry

To the Editor of Chemical & Metallurgical Engineering

SIR:—I was very much interested to read in the last issue of your journal the short article on page 310 entitled "Athletics and Chemistry." In reading the article I immediately thought of the captain of the track team at the University of Illinois, John Prescott.

Mr. Prescott was graduated from the university in June, 1921, in the course in chemistry given here. You probably know the standing of the school of chemistry at the institution. He was a member of one of the largest and best-known college fraternities and was interested in a number of activities outside of his scholastic work. He was a member of "Pierrots," a campus opera organization, on the student council of the Illinois Union, elected to Ma-Wan-Da, the highest senior honorary society for activities, and the Tribe of Illini, an organization of athletes who have been awarded "I"s. In addition to these societies, he was elected to two honorary scholastic fraternities, Phi Lambda Upsilon, national honorary chemical fraternity, and Phi Beta Kappa for excellence in scholarship in the College of Liberal Arts and Sciences.

¹Belalew, "Crystallization and Structure of Steel," Thesis, Petrograd, 1909, p. 48. See also Belalew, "Damascene Steel," *J. Iron and Steel Inst.*, 1918, p. 417.

²Thesis, p. 25.

³Thesis, p. 29.

⁴Thesis, p. 48-56.

Prescott was a member of the varsity track team for three years, and was captain of the team his senior year. His best work was in the 220 low hurdles, but he does the "hundred" in "ten flat" and has done some distance work, being on the conference champion mile relay team in 1920. He captained the University of Illinois track team this past spring to the championship of the "Big Ten" conference, and then took his team to the national meet in Chicago on June 18, winning this meet and the championship of the United States.

He is a rare combination of quiet, likable personality, consistent athlete, par excellence student and chemist.

FRED H. TURNER,

University of Illinois.

Chief Clerk.

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENOA, Italy, Sept. 6, 1921.

THE last five weeks has seen some activity in the Italian chemical and metallurgical market, although from the 7th to the 21st many operatives and employees were absent from the works on account of the summer holidays and the lire suffered a reduction in value, bringing down considerably the price in dollars or pounds of the chemicals manufactured. The lire prices of Italian and other chemicals did not, however, increase in all instances; some remained unchanged and others fell, in response to the volume of offers received from abroad, the heavier or lighter import duties, or the demand.

HYDRO-ELECTRIC DEVELOPMENTS

The construction of the hydro-electric plant that is destined to use the waters of the Lys is proceeding very satisfactorily, the principal difficulties having been overcome. The plants in the recently annexed Trento territory are fairly numerous. One of these is on the Sarco River and produces electric energy amounting to 15,000 hp., which is to be raised to 35,000 hp. in the next twelve months. Another, on the Ponale River, was destroyed during the war, but will soon be repaired and will produce 40,000 hp. There is a hydro-electric plant in the valley of the Flemme, on the River Avisio, which is used to work the mines of the Pedrazzo Works. Its 8,000 hp. will be brought later to 70,000, by the artificial creation of three new waterfalls. Besides these there is a hydro-electric plant of 40,000 hp. in the Venosta Valley (Etsch Werke) and several smaller ones.

ITALIAN FERTILIZERS

The Italian superphosphate industry, although supplying all national needs, is still greatly dependent on importations of the mineral phosphates, as can be gathered from the most recent statistics. During 1918 Italy imported 23,213 tons of such products, in 1919 44,932 tons and in 1920 40,000 tons. For the first four months of this year the importations reached 24,205 tons, against 12,605 tons for the corresponding months of 1920 and 14,050 in 1919. The largest quantities of mineral phosphates came from Tunis (22,077 tons) and from Egypt (517 tons). The demand for superphosphates is still low, owing to the fear of many that the prices will suddenly drop; for this reason very little was accomplished for the autumn and winter treatment of the ground. The same was the case with Italian cyanamide. This product, made either synthetically or from calcium cyanide, has been subjected

to a higher importation duty, to encourage its local production. The importations of superphosphates increased during the first four months of 1921, reaching 322 tons out of a total of 5,405 tons of fertilizers imported. The importation of Thomas slag also increased considerably in that period, being 5,117 tons. In the case of ammonium salts the importations reached 202 tons in the first four months of the year, against 392 tons in 1920 and 3,271 tons in 1919 during the corresponding months.

ITALIAN SULPHUR

The crisis in the Italian sulphur industry became more acute during August, culminating in the strike of some of the miners, who refused to accept a decrease in wages in view of the fact that the price of food had increased considerably. A few days from the time this is written a conference will be held at the Ministry of Industry at Rome between the principal representatives of the industry and the representatives of the workpeople. After this meeting the Italian Government will study the situation and endeavor to find a remedy to offset the increased cost of production.

CARBONATE OF SODA

The manufacture and exportation of carbonate of soda received but little attention in the past, as can be gathered from the fact that Italy imported 34,252 tons in 1920, against 27,234 tons in 1919 and 22,651 tons in 1918, and exported only 66 tons in 1920, 26 tons in 1919 and 25 tons in 1918. The importations made in 1920 were distributed as follows: From the United States, 6,972 tons; from France, 15,967 tons; from England, 4,916 tons; from Spain, 3,278 tons; from Switzerland, 2,253 tons, and from other countries, 865 tons. This year, however, the case has been different, for during the first four months the importations were reduced to 1,836 tons, as against 10,447 tons in 1920 and 6,943 tons in 1919 during the corresponding period.

ITALIAN SOAP INDUSTRY

The Italian soap industry has been greatly developed since the war. In 1920 6,140 tons of common soap was exported to Albany, Austria, Czechoslovakia, England, Greece, Jugoslavia, Poland, Rumania, Switzerland, European Turkey, Asiatic Turkey, Egypt, Tripoli and other countries, while the importations amounted to only 5,690 tons. The exportations of perfumed soaps reached 230 tons in 1920, against 401 tons in 1919 and 24 tons in 1918, and the importations amounted to 739 tons in 1920, against 808 tons in 1919 and 1,549 tons in 1918.

ITALIAN MATCH INDUSTRY

Several of the Italian match factories closed their works after announcing a reduction of wages, made necessary by the reduced demand on the part of the government and by the low profits made on exportations. This led to a meeting, at the Ministry of Industry at Rome, of representatives of the workpeople and of the industry, which is under the direct control of the government. Several discussions have also taken place in the Italian Parliament, but no solution of the difficulty has yet been reached. A new match factory has been started at Turin, which will manufacture exclusively for export. The exportations of matches from Italy in 1920 were 1,033 tons, in 1919 757 tons and in 1918 1,957 tons, but during the first four months of this year they were only 110 tons, against 458 tons for the corresponding months of 1920.

The Seventh National Chemical Exposition

Report of the General Meetings and Technical Sessions of the Exposition, Which Included Symposia on Crushing, Grinding and Pulverizing, Evaporating and Drying, Paint and Varnish, Ceramics, Chemical Power Plants, and American Dyes and Colors

THE Seventh National Exposition of the Chemical Industries was formally opened Monday evening, Sept. 12, with a brief address by Dr. Charles H. Herty. He spoke of the new spirit which is unifying the chemical industries and welding them into a mighty organization, with the single purpose of serving our country in time of peace, or if need arise, in time of war. If the industries are to serve these vital needs, they must be conserved, not alone by the chemist, but by the people acting through their representatives in Congress.

CHEMICAL PROGRESS AND OUR NATIONAL DEFENSE

The importance of chemical progress to the national defense was discussed by Senator Irvine L. Lenroot, who is a prominent member of the Committee on Military Affairs of the United States Senate. The Senator has long been a friend and supporter of chemical warfare and has had occasion to observe its progress and development. He declared that the recent bombing tests had convinced him that the airplane, the airplane carrier, the submarine, poison gases and high explosives will be the implements of war of the future. In referring to the work of the coming conference on disarmament, Senator Lenroot said: "We may agree upon a limitation of battleships, a limitation of submarines, a limitation of airplanes, a limitation of armies, a limitation of the quantity of the war material that can be kept on hand, but we cannot agree upon a limitation of brains, and if we could the limitation would be worthless."

He concluded his address with an appeal for continued research and development in order to insure a reserve of chemists and of chemical plants that can be

converted to the manufacture of explosives and gases should the need arise.

PREPAREDNESS AND CHEMICAL DISARMAMENT

General Amos A. Fries, head of the Chemical Warfare Service of the U. S. Army, who followed Senator Lenroot, declared: "There can be no complete disarmament while any country is operating its chemical factories. Therefore each country must develop its resources along chemical lines.

"The world today demands and will have dyes, photographic chemicals, perfumes and medicines. If we do not produce these substances, other nations will, and by the possession of plants for their manufacture, the nations are equipped to produce the most deadly weapons of war." General Fries declared further that disarmament is only an economic measure, not an insurance against international conflagration. "No disarmament treaty could presume to forbid the manufacture of these necessities of civilized life. Therefore disarmament cannot disarm. It may limit the size of navies, the size and number of guns, but it cannot prevent any nation advanced in the chemical arts from swiftly utilizing its dye plants for the manufacture of destructive gases and explosives."

PROTECTION FOR THE CHEMICAL INDUSTRY

That there are Members of Congress who thoroughly realize the importance of the dye industry was clearly demonstrated Tuesday evening in the address of Congressman Fred S. Purnell, of Indiana. The speaker declared that "just as the World War was the means of bringing to the attention of the world the remarkable

achievements of American chemistry, so a calm deliberation will show us our immediate duty. America has taken the lead in the world's chemical industry. That position must be sustained not only as a potential element of preparedness but as a peace measure. The coal-tar industry and the science of chemical warfare are so closely allied that it becomes our paramount duty to protect the dye manufacturer. The military strength of a nation will in the future depend almost entirely upon its dye plants."

In explaining his personal attitude toward the Longworth bill, Mr. Purnell said: "If we are to save this industry we must act now. Being an old-fashioned protectionist, it is not hard for me to advocate a measure of protection which will amount to an embargo. If the industry is not saved now and encouraged as well as fully protected, American capital will never go into it again and world monopoly will be returned to Germany for all time."

THE CHEMICAL INDUSTRIES AND THE TARIFF

The unprecedented interest of the chemical industries in tariff matters was probably responsible for the large attendance at the general meeting, Wednesday evening, when Dr. Thomas Walker Page, chairman of the United States Tariff Commission, delivered an address on "The Chemical Industries and the Tariff." Commissioner Page prophesied that more time will probably elapse between the introduction of the present tariff bill and its final enactment than has been required for any other tariff in a generation. The chemical industry has been acutely disappointed because of this apparent failure of the bill, and perhaps has failed to realize all of the serious difficulties confronting the tariff maker. The first of these is that it has been practically impossible to estimate the competitive strength of many of the war-developed industries. The growth of new processes abroad, such as nitrogen fixation in Germany and synthetic acetic acid manufacture in Canada, has complicated the valuation of our domestic industries. Abnormal costs and prices and the futility of ascertaining foreign costs of production have contributed to the difficulty.

A second cause for delay has been the growing friction between the producers of finished products and raw materials.

For example, the highly finished product of the dye industry is regarded by the textile manufacturer as his "raw material." The old fight between farm and factory has changed materially. Agricultural interests, formerly low tariff advocates, are strong in their demands for protection, while many of the Eastern manufacturers who have developed foreign markets for their products are desirous of keeping the rates as low as possible in order not to jeopardize their export trade.

Two other difficulties which add to the tariff maker's problem are the need for accepting goods in payment for foreign debts, and confusion arising from the chaotic condition of foreign exchange.

Commissioner Page discussed the many new features of the tariff bill passed by the House and pointed out the use made by Congress of the information supplied by the United States Tariff Commission. He also took the opportunity to refute in public the statements of Congressman Frear that the Tariff Commission had released its 1920 census of dyes in order "to bolster up this dye provision," and that the release of the report

had been "timed exactly by the commission, which wants the power, which wants the \$100,000 and which is insisting that they are the ones to determine what shall be imported and what shall not." Dr. Page declared that the legislator was hopelessly mistaken in his accusations, for "the Tariff Commission has at no time sought the administrative powers of the various dye bills, but has consistently discouraged Congress from placing such duties upon it, since the Tariff Commission is essentially an informative body and not an executive one."

Crushing, Grinding and Pulverizing Symposium

The subject was introduced by Harry J. Wolf, chairman. The three words, crushing, grinding and pulverizing, he said, have been assigned special technical meanings, which in one sense refer to a general classification of the mineral fragments as to size, and in another sense to the manner in which they are reduced, or to the motion of the parts of the machine designed to accomplish the reduction. He then reviewed briefly the status of the art of crushing, and called attention to some of the more prominent recent advances.

Crushing, Storing and Pulverizing.—L. H. Sturtevant of the Sturtevant Mill Co. in a paper on "Crushing, Storing and Pulverizing" said that during the last decade crushing and pulverizing machinery has become highly specialized, and no longer is the "all-purpose" machine recognized in the modern plant. It has been found that machinery embodying certain principles is necessary to produce certain results, and by deviating from these principles inefficiency and a high-cost product, if not failure, are sure. He then discussed the nature of the materials to be handled, and the machinery and equipment used especially in connection with the phosphate rock industry.

Grinding and Pulverizing With Air Separation.—F. B. Kanowitz of the Raymond Bros. Impact Pulverizer Co. presented a paper on the subject "Grinding and Pulverizing With Air Separation." The author discussed the subject at length, and presented a most complete detailed and exhaustive review.

Dust Collection as Applied to Grinding and Pulverizing Problems.—M. I. Dorfman of the Allis-Chalmers Manufacturing Co. delivered an illustrated lecture on the subject of dust collection as applied to grinding and pulverizing problems. He said that for the solution of a dust-collecting problem there are important facts which must be known before the problem can be handled, and they are briefly as follows: 1. The number and kind of dust producing machines. 2. Their relative location. 3. The quality and character of dust to be handled. 4. The condition and quality of the air or gas carrying this dust. Particularly must be mentioned the amount of moisture present in the air, gas or dust. With the above and a layout of the plant in question, the dust-collecting engineer can determine what will be required in the way of dust-collecting machinery to overcome the problem that exists. He must then determine for himself what velocities will be required to convey the various dusts, what type and size of piping had best be employed, and what type and kind of collector would give the operator the results sought.

Development of Compound Grinding Mills.—H. Schiffin's paper on the subject "The Development of Compound Grinding Mills" was presented by Theodore Pilger. This paper was illustrated by numerous lantern slides indicating the development and design of the com-

pound grinding mill. Following this paper Mr. Abbe stated that the compound mill was introduced by the Abbe Engineering Co. sixteen years earlier than the date claimed for its introduction by the Allis-Chalmers Manufacturing Co., and that the latter company could not claim the credit for having introduced the mill. Mr. Abbe promised to write a letter setting forth the claim he made.

There followed a short talk by Dr. H. H. Dow on the subject of the tariff in its relations to the dye industry, in which he called attention to the desirability of protecting the American dye industry just long enough for it to demonstrate its ability to take care of itself, which, he assured the audience, could be done.

Of the papers which were to be presented on the subject of Industrial Problems only the paper of H. Austin (Ernest Scott & Co.), on "Solvent Extraction on Edible Fats and Oils," was read and as the clock registered 6:15 p.m. there was no time to proceed with the other papers on the program—namely, those by R. H. McLain of the General Electric Co. on "Material Handling in Industrial Plants," and by W. H. Dickerson, of Industrial Waste Product Co., on "Utilization of Industrial Waste; Its Economic Importance."

The chairman made the recommendation to the manager of the exposition, that in outlining all future programs of this character the speakers be positively limited to a fixed number of words or a fixed time available for the presentation of their subjects, so that a large proportion of the time available could not be monopolized by any one speaker. Naturally some of those in attendance come a considerable distance to hear a discussion on a certain subject or to listen to a certain paper, and they are disappointed when the program must be curtailed on account of insufficient time.

Evaporating and Drying Symposium

The symposium on evaporation and drying was held Wednesday, Sept. 14, under the chairmanship of Wallace Savage. In the opening address Mr. Savage said that there are about sixty machinery manufacturing companies producing around two hundred designs of evaporating and drying equipment in this country. One-half of these devote their attention exclusively to driers and one-third to evaporators. About twelve companies produce both. This afternoon we have the pleasure of hearing a number of 15-minute talks giving the basic ideas involved in the leading types of equipment for transforming liquids to vapors and in this form displacing them from solutions or solids, either by air currents or vapor pumps.

SELECTION OF DRYING EQUIPMENT

H. S. Landell, of Proctor & Schwartz, was to present a paper on Drying and Drying Problems, but instead spoke on the understanding and confidence that should exist between a prospective purchaser and the manufacturer of drying equipments. He said that it is always to the purchaser's interest, especially when a new plant is being built, to consult with a reputable drying concern before his plans are all made. Often he thinks of his drying as an incidental process which can be placed anywhere, not realizing that frequently his drying is one of the most important problems. The best way for the prospective purchaser is to give the drying salesman a generous, representative sample of the material to be dried, and at the same time give him all the information possible regarding the preliminary

and supplementary operations. Drying tests will be run on the material furnished, and the drier manufacturer will then be able to submit a proposition for a drying equipment that will be guaranteed both mechanically and as to capacity.

SPECIAL PROBLEMS FOR ENAMELED EVAPORATORS

Max Donauer, of the Elyria Enameled Products Co., in speaking about the special evaporation problems, described briefly the two common types of enameled evaporator—namely, jacketed evaporating dishes and single-effect vacuum pans—and enumerated a series of industries where enameled evaporators are the most appropriate. "The field of enameled evaporators," he said, "is for the most part a special one. It includes those operations in which the presence of an enameled surface plays an important part. Thus enameled evaporators are used for concentrating solutions which contain acids and for preparing products which must be kept free from contamination. The uniform heating conditions make enameled vacuum pans suitable for concentrating sensitive products which are apt to discolor or become caramelized. Enameled surfaces can be readily cleaned, and this makes the evaporators very suitable for food and drug work. Indeed, in the preparation of many of the highest grade food and chemical products, enameled evaporators play an important part."

DRYING WITH MOIST AIR

Arthur B. Stonex, of the Hunter Dry Kiln Co., in his address on Drying With Moist Air said in part:

"To those not intimately familiar with certain forms of present-day industrial drying the title of this paper, 'Drying With Moist Air,' may seem in the nature of a paradox, a contradiction of terms, for obviously moisture is the antithesis of dryness, and so to dry with moist air may at first blush seem as preposterous as to refrigerate with warm air. But drying with moist air will not seem quite so insane a procedure when it is remembered that in nature one never finds air that is not moist, and every one knows that a vast amount of drying, as of the soil and vegetation, is constantly going on. Indeed in many industries where the drying of materials or finished products is necessary so-called natural drying is regarded as the ideal kind of drying.

"Moist air is so desirable for drying at least some materials that it is artificially produced. The principle governing this practice is that the increased absorptive capacity of the air is only indirectly due to the increased temperature—that is, the increased capacity is rather the result of the decreased degree of saturation of the air. The solution of the problem, therefore, is to find for a given material not the maximum temperature, but the minimum degree of saturation or relative humidity at and above which too rapid surface drying will not take place at the highest temperature the character of the material and profit will otherwise permit, and to maintain that temperature and, as long as necessary, that relative humidity.

"By raising the temperature, the vaporization of the water in the material is hastened, but by keeping the relative humidity of the air sufficiently high, the air will not absorb the vapor coming from the surface of the material any more rapidly than at a lower temperature. Indeed, with certain materials it is desirable, and with proper humidity control it is possible, to prevent any surface drying until the stock has be-

come uniformly and sufficiently warm and vaporization has begun throughout the mass. In general it may be said that besides the prevention of destructive surface drying, the maintenance of such relative humidity results in more uniform drying of any material, and that the effects of any temperature above 100 deg. appear to be less severe in a comparatively moist air."

DRYING AS AN AIR CONDITIONING PROBLEM

A. W. Lissauer, of W. L. Fleischer & Co., Inc., in his address on Drying as an Air Conditioning Problem, brought out the fact that drying is still supposed by many to be the simplest branch of all heating and ventilating and that failures are accredited consistently to circumstances which probably have no bearing. He stated that the phenomenon of drying can be explained very easily by the application of the law governing air conditioning—in other words, drying is merely air conditioning—and concluded by saying that the solution of any drying problem which has for its object the obtaining of the highest quality of product with the maximum efficiency can be accomplished if guesswork is eliminated and painstaking study and experimentation be substituted.

CRISS-CROSS EVAPORATOR

A new type of tube evaporator deriving its novelty from a decidedly different tube arrangement was described in an interesting paper on the Criss-Cross Evaporator by Robert V. Cook, chemical engineer and sales manager for the Chemical Equipment Co. The new evaporator is known as the Criss-Cross because of the cross-arrangement of its tubes. This is clearly shown in the accompanying cross-section drawing. It will be seen that the rectangular liquid chamber carries the crossed tubes and the steam chests. The front steam chest is divided in the center by a horizontal partition, so that the steam must descend down the tubes inclined toward the bottom of the back steam chest. That part of the steam which has not been condensed then rises and descends in the opposite direction toward the bottom part of the front steam chest. The condensed steam is drained out of the bottom of both front and back chests. The top of the evaporator, or the vapor chamber, is a cylinder with a vertical axis and has several times the volume of the liquor chamber. This allows the vapor to slow down, to expand and to drop out the entrainment. A standard save-all is employed to make sure that no liquid will be drawn out along with the vapor. In this particular evaporator there are ninety-six $\frac{1}{2}$ -in. seamless drawn copper tubes, 32 in. long, giving 33.5 sq.ft. of heating surface. They are arranged in two groups, half being inclined downward toward the right and half inclined downward toward the left, the rows being staggered, as shown.

Mr. Cook explained a number of advantages claimed for the new evaporator and referred to the possibility of applying the same principle to preheaters, boilers, surface condensers and different forms of heat-exchange apparatus.

VACUUM AS APPLIED TO INDUSTRY

James S. C. Chen, of the J. P. Devine Co., spoke on Vacuum as Applied to Industries. He said that vacuum drying, which was used only in limited fields in the past,

has in recent years attained a position of such importance in the chemical and allied industries that it is worth while to make a thorough and comprehensive study of the subject. At present vacuum drying is extensively used in the chemical and allied industries not only because its use is in many instances imperative, but because its use is efficient, economical and insures superior and uniform quality of the finished product. Vacuum drying has found extensive application in the drug and dye industries and in drying fruits, vegetables and dairy products. His closing remark was that no modern industry can long prosper or even survive without giving constant attention to the improvement of its method of production and refining and to the quality of its products.

ATMOSPHERIC DRYING: COMPARTMENT, TUNNEL AND CONTINUOUS BELT CONVEYOR DRIERS

Jerome D. Stern, of Grinnell Co., Inc., Drier Division, summarized his address on Atmospheric Drying by Means of Compartment, Tunnel and Continuous Belt Conveyor Driers, With Some Practical Applications, by saying:

"The physical and chemical characteristics of the wet

FIG. 1. SECTIONAL VIEWS OF THE CRISS-CROSS EVAPORATOR

and dried product are the primary factors in deciding on the proper type of drying equipment to install. The most efficient method of handling the material, the air temperatures, volumes, velocities and humidity are all dependent on this deciding factor, and unless one has wide experience with the nature and conditions of the product, or as a result of thorough and exhaustive laboratory tests, it is a waste of time to make any calculations or recommendations until these are absolutely determined."

EVAPORATION

H. Austin, of Ernest Scott & Co., presented a paper on Evaporation in which, after reviewing the various problems pertaining to evaporation and to the selection of an appropriate evaporator, he outlined some of the

characteristics of the Scott evaporators. He concluded by saying:

"'Evaporation' is in effect 'distillation,' and in the distillation of oils in which different fractions separate at a known fixed temperature and vacuum, evaporators using steam heat may, with advantage in cost of outfit and operating costs as well as more easy control, be used instead of ordinary type stills using fire heat. Benzine, gasoline, naphtha, etc., can, with advantage, be evaporated, distilled and fractionated in machines similar in design and construction to those more commonly associated with the evaporation of water."

Paint and Varnish Symposium

Thursday, Sept. 15, was Paint and Varnish Day and the well-arranged programs attracted large audiences. The afternoon technical session was followed by a popular meeting in the evening on the theme, "Save the Surface and You Save All." Ernest T. Trigg, chairman of the "save the surface" committee, Paint Manufacturers' Association of the United States, acted as chairman and delivered a most interesting address on the aims and accomplishments of this campaign.

At the paint and varnish symposium, which was presided over by R. S. Perry, the following papers were presented:

LABORATORY CONTROL

Scientific control of paint and varnish manufacture was discussed by Leo P. Nemzek, of E. I. du Pont de Nemours & Co. He spoke in part as follows:

While laboratory control has its most direct association with production, there are many points of contact with the sales department. Successful operation is measured largely by the contact with sales, and through them with the ultimate consumer. The paint technologist must know what the consumer requires from a point of service, and what he desires from a decorative point of view.

The handling of complaints offers one of the best avenues of sales department and laboratory co-operation. Nine out of ten complaints are due either to paint improperly applied as to time, surface condition, or workmanship, or else the proper paint was not selected for the job. Yet in the handling of a complaint, there is an excellent opportunity for displaying much tact and patience, besides bringing out all of the recorded facts and information available on the subject involved.

The major function of laboratory control is associated directly with production. The first requisite is a thorough knowledge of the products in which the different raw materials are used. A raw material record should be maintained, which immediately shows all products in which a particular material appears. This record is necessary in raw material development work, in advising the works where certain shipments of raw materials may be used to best advantage. The record is essential in the adoption of raw material substitutions which are occasionally necessary.

Laboratory control must exercise a close check on new formulations. This may be a part of control work, or merely come under the general supervision of the chief chemist. A properly kept products index will help to keep down the formulation of new paints. Such an index shows in a moment a list of products of the same character or similar nature to the material under consideration.

The greatest value of the index lies in the standard-

ization of formulas. All products of a certain type should be composed of the same ingredients. A thousand enamel formulas will vary only in the pigments necessary to give desired colors. The vehicle will consist of half a dozen standard varnishes, and not twenty or thirty, which might very easily be the case if standardization of formulas is not watched.

This holds true for ready mixed production, but the situation is reversed when it comes to pastes. Then the practice is not economy. There are cases where the use of two or three standard bases in producing a paste product means increasing the cost 10 to 15 per cent over what it would be if the formula ingredients were put together separately.

Laboratory control requires first of all a thorough knowledge of:

1. The user's requirements of the paint and varnish.
2. The chemical and physical properties of available raw materials. How they react one with another, and what different combinations develop on aging.
3. Possessing the first two requirements: control or supervision over the formulation of the most economical product that will give satisfaction.

Development work is essential both on raw materials and finished products. The field for research is large. The work that should be done is suggested by the conditions that arise in the usual routine functioning of technical control. The strictly routine functions of laboratory control are the checking of all raw material shipments and finished products so as to insure uniformity.

REFLECTION FACTORS OF INDUSTRIAL PAINTS

Dr. Henry A. Gardner presented a paper on reflection factors of industrial paints and pigments.

In computing the reflection factors of industrial paints, the factor 0.98 should be used for magnesium carbonate (the standard) rather than 0.88, and earlier measurements should be corrected accordingly. For instance, the reflection coefficient of a white paint which previously may have been reported as 76 should be corrected to read 85. The possibility of having walls in factories so painted that they yield by reflection 85 per cent of normal light is of great importance to the architect and owner. Figures for a few industrial flat and gloss paints now marketed are given in Table I. It will be noted that some of them run as high as 82 per cent, a figure extremely high in comparison with similar type paints marketed several years ago. This great advance in the production of interior industrial whites of high illuminating value has come as a result of many years of careful study and selection of the pigments and liquids available for the purpose.

TABLE I. REFLECTION FACTORS OF MODERN INDUSTRIAL WHITE PAINTS

	Coefficient of Reflection*		Coefficient of Reflection*
Exterior white oil paint	71	Gloss mill white XX...	76
Non-darkening exterior oil paint	78	Gloss mill white XXX.	82
Gloss mill white X	74	Flat mill white.....	78

* On basis of 98 for magnesium carbonate.

White paints may show a small loss of reflection value after remaining in a dark place for several years, due to yellowing of the oil content. This loss, however, is probably much less than would occur when paints become darkened due to dust adherence, even over a short period

of time. For the walls and ceilings of factories a paint is desired that will initially and permanently give the highest degree of reflection. Off-color products or those that show rapid yellowing of the oil content are considered unsatisfactory. Tinted and colored paints may or may not show a loss in reflection value upon aging. The result will vary with the type of tinting color used.

White opaque pigments vary in reflection value. It would appear that the greatest reflection is obtained from pigments with the greatest opacity.

For determining the reflection factors of industrial paints, it is suggested that two coats be applied under standard conditions to black iron surfaces previously coated with a continuous coat of flat black primer. For this purpose, the same amount of each paint should be applied, as determined by weight of paint applied.

An example of the results obtained by this method will be found in Table II. In this series of tests, the pigments were ground in a liquid consisting of one part of flattening varnish and two parts of turpentine. The paints contained 60 parts by weight of pigment and 40 parts of liquid, since it was impossible to make a

TABLE II. REFLECTION FACTORS OF CERTAIN WHITE PIGMENTS

Pigment	Coefficient of Reflection When Applied in Flat Liquid	Coefficient of Reflection, Compressed Dry Pigments
Lithopone (A grade)	81	91
Titanium pigment	78	91
Zinc oxide (French process)	78	91
Zinc oxide (5 per cent lead)	77	87
Lithopone (Grade B)	69	89
White lead, Type A	67	90
White lead, Type B	50	90
Calcium carbonate	38	90
Silica	19	88
Barium sulphate	13	88

workable paint with over 60 per cent of certain of the pigments employed. Two heavy brush coatings were applied to a series of sheet-iron panels, one hour being allowed between coats. The panels had previously been coated with a perfectly black, flat paint having a reflection coefficient of about 5. The great hiding power of the opaque white pigments was at once evident from the appearance of the finished panels. The inert pigments, on the other hand, had but little hiding power, in comparison.

For comparison, the reflection factors of the dry pigments are given in the second column of Table II. It should also be borne in mind that the hiding power of a paint depends largely upon the liquids chosen for the vehicle portion. The greater the difference between the refractive index of a liquid and that of the pigment the greater will be the hiding power of the paint.

This paper by Dr. Gardner has been published as Circular No. 133, Educational Bureau, Paint Manufacturers' Association of the U. S.

PHYSICAL TESTING OF PAINTS

Frank G. Breyer, of the New Jersey Zinc Co., called attention to the fact that the physical testing of paints and paint materials has not received attention commensurate with its importance. He made a plea for a rational development program for paint technology based on five fundamental factors—suspension (mixing or incorporation), life of suspension, application, conversion of applied material to adherent film and life of film.

PAINT AND VARNISH WASTE CONTROL

R. S. Perry's paper on "Paint and Varnish Waste Control" was read by his associate, Paul Webster. The

fume recovery process developed by this firm has been described in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 23, p. 771, Oct. 20, 1920, and many of the views shown by Mr. Webster were included in that article. Other installations described and illustrated by Mr. Webster were those of the Patton-Pitcairn Division, Pittsburgh Plate Glass Co., Milwaukee, Wis., and Breinig Bros., Inc., Hoboken, N. J.

THE IDEAL PAINT AND VARNISH SPECIFICATION

F. P. Ingalls' paper on "The Ideal Paint and Varnish Specification" will be found in full on page 595 in this issue.

LIMITATIONS OF STANDARDIZATION

The limitations of standardization of paint and varnish manufacture were considered at some length by D. A. Kohr, of Lowe Bros. Co. He said in part:

Very few of the products of the paint maker are made on absolute formulas; it has even been said that paint formulas serve merely as guides, and in a large measure this is true, because almost every batch of paint must be modified by the addition to it of small quantities of this, that or the other raw material before the batch is ready to pass final inspection. Accordingly most paint manufacturers have learned by experience to pay scant attention to the applicant for a position who shows as his chief recommendation a collection of someone's formulas. Almost anybody can mix together raw materials in accordance with a formula, but before the resulting mixture can pass muster as a paint of quality it must be given the careful attention of an experienced paint maker.

The same raw materials from the same sources of supply, as they are furnished to the paint maker, will not when made into a paint always produce a product that has the same properties—in fact, the resulting product is much more apt to vary than it is to be uniform. The consumer expects different lots of the same paint to be uniform and when the difficulties overcome are considered, different lots of the same paint from a reputable manufacturer are wonderfully uniform; but their chemical composition is not uniform within close limits and, if best results are to be obtained, it cannot be made uniform.

The paint and varnish industry differs from the automobile industry, for example, in an important respect. Whereas the automobile manufacturer turns out a product that is ready for the ultimate consumer to use, the products of the paint and varnish maker must first be applied by a painter or finisher to some surface owned by the consumer, and then be allowed to undergo the chemical and physical changes commonly known as drying and hardening before they can fulfill their real purpose. Hence what the paint and varnish manufacturer is actually furnishing the consumer is not paint and varnish, but beautification of his property, as when a piano is beautifully stained and varnished; or protection to his property, as when an expensive bridge is painted to prevent corrosion of the steel; or both, as when a man has house paint applied to his own residence.

A vast amount of work has been done by many manufacturers in designing a fairly large number of excellent products which when intelligently used will give fine results. Is it therefore not reasonable to suggest that consumers who certainly know less about paint making than paint manufacturers will more quickly

bring about the desired end of securing uniformly good results from painting, if they turn their energies from the question of standardizing the composition of paint and give more attention to the control of those factors that have an influence on the final result equal to that of the paint and which are entirely beyond the control of the manufacturer? When a consumer is sure that paint is applied only to clean, dry, warm surfaces under suitable weather conditions, and by mechanics who are fully competent and experienced, then, and only then, can he profitably consider whether he can specify a paint that will be better than the one offered by a reputable manufacturer as the result of his long experience and observation under many varying conditions.

American Ceramic Society Meeting

The American Ceramic Society meeting was held Friday, Sept. 16. Among the papers presented were the following:

Business Conditions Relating to the Clay-Working Industries.—John G. Jones spoke on the outlook for the clay products industry. The chief problem at the present time is to fix prices at a level which will appear attractive to customers. A clear statement is needed of the difficulties in the way of reducing prices. The cost of fuel is still 100 per cent above the pre-war level owing to the fact that the wages of the coal miners have not yet been reduced. Freight rates are still high. Materials used in manufacture have not declined in proportion to the rest of the commodity list. It is not difficult for steel mills to cut wages, because they are dealing with common labor, poorly unionized. Clay producers, on the other hand, must deal with skilled workers, highly unionized. For these reasons the present price of clay products is not unreasonable. There has been a reduction of 40 per cent from the peak prices. The approaching demand in many lines promises a revival of trade near the present price levels during 1922.

The Importance of Chemical Stoneware in the Chemical Industries.—Percy C. Kingsbury said that although chemical stoneware is a small branch of the ceramic industries, it is of great importance to chemical plants. No stoneware body can meet all the varied requirements of the chemical industry, and it is therefore necessary to furnish a wide range of stoneware products from the firebrick-like mass at one extreme to the porcelain-like mass at the other. Chemical stoneware is unaffected by any of the products met with in industrial chemical work, with one or two relatively unimportant exceptions. The glaze serves only to give the ware a smooth surface and does not add to its acid-resisting properties.

The Passing of King Methane.—S. R. Scholes, in speaking of the depletion of gas in the clay districts, said that forty years ago natural gas, which is chiefly methane, was regarded as a nuisance encountered in drilling for oil, but it became the most important glass-house fuel, and its abundance and excellence gave rise to the prosperous glass industry of the Ohio Valley. It has been wastefully used, and is now so scarce and expensive, especially in cold weather, that other fuels such as producer gas and fuel oil are replacing it. Even in the best glass-melting tank furnaces, less than 10 per cent of the heat of the fuel finds its way into the glass; 20 per cent goes up the stack and 70 per cent is lost by radiation. With the present refractories this high radiation loss cannot be stopped by heat insula-

tion, because of the consequent melting or failure of the refractories. These must be improved so as to bear insulating. Also there must be better engineering work done on designing furnaces for the best heat economy, so that the successors of "King Methane" need not be burned with the same prodigality that has wasted our resources of natural gas.

Porcelain for the Laboratory.—Charles F. Binns defined porcelain for the chemical laboratory, for it differs from china, even though both are white and translucent. He described its origin and method of manufacture. It was produced in common with most ancient wares by a reducing fire, involving a refractory glaze. Methods of production in America and Europe were compared. Mixture of porcelain glaze was contrasted with lime-soda glass and mixtures of chemical porcelains were compared with china and earthenware.

Heavy Clay Products Research.—Maurice B. Greenough of the National Paving Brick Manufacturers' Association and secretary-treasurer of the Joint Clay Products Research Committee spoke on heavy clay products research. The Federal Government through its bureaus, the scientists of the clay products industry through the American Ceramic Society and the manufacturers of facebrick, hollow building tile, common and vitrified paving brick through a joint committee of their respective national associations have all joined hands to seek by research to solve vital problems in heavy clay products production. The scope of work has been defined and assignments have been made to each group. The financial support is assured and the program is in operation. The program differs materially from the general run of such efforts. In the first place, the public is represented and has an interest exercised through the work that is being done in the Government bureaus. The buyer co-operates with producer in the improvement of processes and the bringing about of more economical industrial operations. The operations of the program are beginning with studies of existing equipment. Present kiln types must be employed with greater efficiency. Practical considerations are foremost in promoting the studies. The preliminary stages of the whole organization are passed and nothing but hard work lies between the present and the ultimate attainment.

The conference on the program of the American Ceramic Society activities held at the Hotel Commodore Sept. 15-17, will be reported in a later issue of CHEMICAL & METALLURGICAL ENGINEERING.

Symposium on the Power Plant in the Chemical Industries

The Symposium on the Power Plant in the Chemical Industries was held Friday afternoon under the chairmanship of R. C. Beadle, editor of *Combustion*.

Mr. Beadle in his opening address brought out the facts that about 10,000,000 tons of coal is used yearly by the chemical industries and that by the introduction of mechanical coal firing the fuel efficiency has increased to about 85 per cent from an efficiency of only about 50 per cent with hand firing. He predicted that before many years have passed the fuel used in the chemical boiler plants will be a byproduct of the raw coal.

Description of a Modern Boiler Plant and Equipment.—R. M. Gordon, manager of the steam supply and testing departments of the Solvay Process Co. at Syracuse, N. Y., gave a detailed illustrated description of the

water purification, coal preparation and boiler house at the Solvay Process plant, where all the principal operations are metered or recorded so that the efficiency of the plant can always be calculated and is figured and charted each month. Daily outputs are carefully watched. The efficiencies for the past six months are as follows:

	Per Cent
Boiler and furnace.....	77.5
Boiler, furnace and economizer.....	82.2
Plant efficiency	85

How Heat Losses in Chemical Plants May Be Reduced.

—John Primrose, vice-president of the Power Specialty Co., of New York, spoke on how heat losses in chemical plants may be reduced. He said in part: Modern engineering practice has recognized the importance of good combustion, and means are now available for more completely burning the fuel before attempting to recover any of the heat produced by combustion. After the fuel is properly burned, the next consideration is to absorb the heat produced.

Of all methods of supplying heat in process work probably the most economical is heating by saturated steam where the steam is condensed and the resulting hot water is returned to the boiler. This is limited to processes that do not require a temperature higher than is available with saturated steam, say, 300 deg. F. Above this temperature, up to 600 deg. F. or higher, superheated steam may be used, and if the steam can be used in turbines or pumps, etc., after it has served its purpose as a heating medium and the exhaust is used in heating feed water, the economy is almost as good as with saturated steam. Each individual problem is worthy of study by engineers, not necessarily chemists, but who by training and experience have obtained knowledge of heat engineering beyond that usual in the chemical industry itself. Such studies, it is reasonable to expect, would bring about that very much desired result—a reduction in manufacturing cost.

Compressed Air Installations in Industrial Plants.—

A. R. Stevenson, Jr., of the power and mining engineering department, General Electric Co., spoke on compressed air installations in industrial plants. He outlined the appropriate uses for single- and multi-stage centrifugal compressors, rotary displacement blowers and reciprocating compressors. In almost any chemical plant there are liquids to be moved. Compressed air is used extensively for such pumping. He touched on the three fundamental systems in use—namely: 1. Air lift, 2. Pneumatic displacement pump, 3. Return air system, and stated that these three systems are especially good for dye works, bleacheries, pulp mills, and for handling solutions, because there are no moving parts, lubrication or packing and they are therefore not affected by muddy or gritty water.

Application of Electric Power in the Chemical Industries.—The paper on the application of electric power in the chemical industries, by D. B. Rushmore, J. A. Seede and E. Pragst, of the General Electric Co., consisted of a lengthy discussion of the uses of electricity in electrothermics, electrolysis, for transformation into mechanical power and in the specialized applications such as magnetic and electrostatic treatment, ultra-violet rays, X-rays and others of small application but great possibility.

After passing in review the field of electrothermics, the sources of primary power and the problem of pur-

chased power versus isolated plants, they outlined at length the practice in steam-electric and hydro-electric generating stations and concluded as follows:

"The chemical industry is at present one of the most fruitful fields for electrical application in the future. It is fruitful not only from the point of view of those engaged in the manufacture and sale of electrical apparatus, but particularly from the standpoint of pure engineering, for it is forever presenting to the electrical engineer problems of a most diversified interest—problems ranging from heavy currents at low potentials to the opposite conditions of low current at high potentials, with alternating and continuous current; problems where the frequency ranges from 5 cycles to 10,000 cycles per second; problems involving X-rays, ultra-violet rays and other means of accelerating reactions; problems of insulating materials to withstand the effects of heat, corrosive gases and acids; problems involving the maintenance of continuity of service and the low cost conversion of energy; problems of processes and methods, etc. It is this diversity of interests of the industry, its problems and the rapidity with which it is expanding, that makes it appeal so strongly to the electrical engineer as an outlet for his productive efforts. Obviously the greatest advance will be made when the co-operation is most complete between the chemical and electrical engineer and, as the former has solved many difficult situations for the latter in the past, the electrical engineer will continue to reciprocate, especially along those lines that will materially assist in promoting our national well being."

The Limitations of Silent Chain Drive.—Some general and specific data on the design and use of silent chain drives were presented by F. G. Anderson, of the Morse Chain Co. He stated that the silent chain drive has gradually won on its merits until it is now generally considered by competent engineers a standard drive for practically all of the ordinary power transmissions between parallel shafts and gave as definite reasons: Reliability, positive speed ratio with flexibility of operation; possible short center distances, minimum attention required, high efficiency and quiet running.

Pulverized Coal in the Power Plant.—H. G. Barnhurst, of the Fuller Engineering Co., spoke on pulverized coal in the power plant. He said that the use of pulverized coal in preference to grate firing presents the following advantages: Higher efficiencies are obtainable. The reliability of the plant is increased by the much greater range of fuel which may be satisfactorily burned. Labor is greatly reduced and control of boiler operation simplified. Considerable economies are present in the elimination of standby losses and loss of carbon in the ash, and the boiler flexibility is increased very considerably. The use of pulverized coal in chemical and metallurgical furnaces is gradually becoming a standard method of fuel firing.

Other papers on the program were:

"Boiler Feed Water Treatment and Treatment Control," by E. C. Bashore of Rice & Bashore; "A New Method for Coking Coal as Required for Industrial Fuel," by D. S. Chamberlin, of the Distillation Industries, Inc.; "The Application of Pulverized Fuel," by H. D. Savage, of the Combustion Engineering Co.; "The Prevention of Internal Corrosion in Pipes, Tanks, and Other Iron and Steel Equipment," by Perry West, of the Anti-Corrosion Engineering Co., and a short talk on "The Master Key Industry," by Dr. Charles L. Parsons, secretary of the American Chemical Society.

Is There an American Dye Monopoly?*

BY FREDERICK E. BREITHUT

MANY good Americans are of the *opinion* that there is a monopoly in the dye-making industry. What are the *facts*?

The accompanying maps show:

1. In 1914 there was no real dye manufacturing in the United States—simply seven small plants in three states, assembling German intermediates into dyes.
2. In 1920 there were eighty-two American dye plants located in eighteen states.
3. In 1920 there were 213 coal-tar chemical plants located in twenty-five states.

1914—Total, 7

1920—Total, 82

LOCATION AND NUMBER OF PLANTS MAKING COAL-TAR DYES IN THE UNITED STATES

In this connection it may be interesting to submit two quotations from official Government reports.

The first is from "Artificial Dyestuffs Used in the United States," by Thomas H. Norton, Department of Commerce Special Agents Series 121, published in 1916:

"The manufacture of coal-tar colors in the United States has been in existence about thirty-seven years. Prior to 1915 it had never become a factor of importance in supplying the American market. The American manufacture was confined almost entirely to the 'assembling' into finished dyes of coal-tar intermediates imported from Europe, chiefly from Germany. In its entirety it represented less than one-tenth of the activity to be encountered in any one of the larger companies producing synthetic dyes in Germany and Switzerland."

Contrast this picture of national dependence with that presented by the following quotation from the United States Tariff Commission's Census of Dyes and Coal-Tar Chemicals, 1920:

"The total number of firms engaged in the production of coal-tar products in 1920 was 213, while those companies engaged in the manufacture of dyes alone numbered 82."

The Tariff Commission has made a study of the number of firms producing each dye, which reveals significant facts concerning the organization of the domestic industry. Three hundred and sixty separate dyes were manufactured in 1920. Of these, 108 dyes, the output of which represented more than 90 per cent of the total production, were *each* manufactured by three or more firms. Of greater importance, however, is the fact that those dyes, representing over one-half

of the total quantity produced (thirty-five in number), were *each* manufactured by seven or more firms.

Even a cursory glance at the figures in Table I reveals:

1. That the number of independent manufacturers of each of these large-tonnage dyes is sufficient to deny the existence of a monopoly.
2. In general, prices have shown a steady downward trend (of course there are a few specific instances in which other factors, such as rise in raw material costs and imperfections in process control, make this general tendency inoperative).

What about the intermediates from which dyes are made? Let us begin with a specific example. You are

all familiar with the substance known as naphthalene. It is commonly used in the form of moth balls. This commodity is one of the most valuable of coal-tar chemicals. According to the 1920 census there were forty-six important intermediates made from this coal-tar crude. The number of manufacturers producing each of these commodities is indicated in the following table:

Name	No. of Mfrs.
2-Naphthol-3:6-disulphonic acid	16
1-Amino-2-naphthol-4-sulphonic acid	13

No, there is no American dye monopoly! Our dyes are being made by many manufacturers, some very large, some very small. They are all selling against one another in open competition. As a matter of fact, every manufacturer who is actually in the business knows full well that the competition is not only in the open, but that it is really much fiercer than in most lines of business. Anyone is at liberty to go out with the salesmen of our dye companies, and we are convinced that a few days' experience will convince him

that there is absolutely no monopoly in existence. If there were such a monopoly, it would seem that it must be very inefficiently managed to permit ten, twenty and thirty different independent plants to produce the same product, and also to permit a consistent reduction of prices throughout the list of the products which it manufactures. Increasing the output, decreasing the price and permitting the existence of many plants producing the same article, thereby giving employment to a greater number of persons, are actions not usually ascribed to a monopoly.

If you will take the trouble to look through the capital investments of our eighty-two dye-makers, you will find that they vary from a few thousands to millions of dollars. An examination of the names on the boards of directors shows that there are no interlocking directorates nor other forms of commercial control.

The truths enumerated above are simply so, and it is very difficult to believe that those who persist in reiterating that there is an American dye monopoly can be doing so through sheer ignorance of the facts.

The Ideal Paint or Varnish Specification*

BY F. P. INGALLS

Chief Chemist, John W. Masury & Son

IN DISCUSSING the ideal paint or varnish specifications it is of course understood that the ideal or perfect specification cannot actually be written until the sum total of our chemical and physical knowledge shall reach the infinite, yet it is wholly rational to discuss such an ideal, and, by overcoming the obstacles one after another, try to approach continuously nearer to it in practice.

Although the larger part of the paint and varnish sold in this country is purchased ultimately by a large number of relatively small consumers, without any specification other than is implied by the brand or assurance of the manufacturer, there are many buyers who, by virtue of some obligation to purchase at the lowest rates or to avoid favoritism in awarding contracts, must accept the lowest obtainable quotations for satisfactory goods. Under such circumstances it is obviously necessary for the buyer to state in clear and unmistakable terms just what goods will be satisfactory or acceptable and at the same time exclude all other or inferior goods. Such a description is called a specification.

THE PERFECT SPECIFICATION

The most nearly perfect specification is that one which, in the fewest words, best describes the desired paint or varnish so clearly and completely that no inferior product can gain acceptance. The ability to write any such specification not only involves a general knowledge of the possibilities of production from such materials and by such methods as are known to be available, but it also implies the existence of ways and means of determining the probable economic value of the delivered goods before they are put into actual service. In other words, the specification must be based on a knowledge of what can be produced, and how to test the

*A paper presented at the Seventh National Exposition of Chemical Industries, Eighth Coast Artillery Armory, New York, Sept. 12-17, 1921.

delivered goods. This is fairly evident, because in any exchange of goods for money or other value the delivered goods must in general be accepted and paid for long before they shall have demonstrated their value in actual service.

It is scarcely to be expected that any one person can have at his command all the knowledge necessary for the best possible specification, nor that a specification which embodies only the knowledge of one person, however expert, will be universally acceptable. In this country, however, we are fortunate in having at our disposal the collective knowledge and co-operative work of Committee D-1 of the American Society for Testing Materials, a committee numbering about 115 members composed of the leading paint and varnish technical experts, producers and consumers, both having about equal representation. The A.S.T.M. is a permanent organization of about 3,000 engineers and technical experts, and its prime object is to prepare specifications and to define standards for engineering materials of all kinds. Any specification issuing from such a body may be regarded as highly authoritative. A number of other bodies are closely allied with it, especially the U. S. Government Inter-departmental Paint Specification Committee, the Paint Manufacturers Association of the U. S. and the National Varnish Manufacturers Association, all of which have direct representation on Committee D-1. With all this aggregation of talent, operative for a number of years past, it is pertinent to ask, Why are so few complete and satisfactory specifications for paint and varnish available at the present time? The answer to this question brings before us a realization of the really formidable array of obstacles encountered, and the large amount of slow, tedious and painstaking work required to overcome them.

Theoretically paint is a very simple thing. It is merely a solid-liquid two-phase physical system composed of any finely divided, essentially inert powder or pigment, suspended in a liquid vehicle which possesses the property of becoming solid upon extensive exposure to the air. In detail, however, it is no such simple thing, but is on the contrary a highly complicated affair with almost infinite possibilities.

GENERAL DIVISION OF PAINTS

The complete list of products of any of our larger manufacturers will show all the way from 300 to 600 or more items, each regularly carried in stock ready for delivery to the purchaser. In addition to these there may be several thousand formulas for special paints or varnishes of one kind or another especially adapted to some unusual or peculiar use. Fortunately these items, although distinct in themselves, may be divided or classified into about fifteen or twenty groups, or lines, of paints and half a dozen classes of varnish, the individuals of each class differing from one another merely in some minor detail, such for instance as color. In a system of classification the difference between the individuals would generally be determined by the pigment present, but the classes would be distinguished by the character and proportion of the vehicle. Paints are therefore usually divided into two grand divisions—namely, paste paints, which require thinning down for use, and liquid, or ready-mixed, paints, which are already thinned down and are practically ready for use; in the first division the proportion of vehicle is as small as is practicable for the grinding process, while in the

second division the proportion of vehicle is much larger and is adjusted so as to give the finished paint the required working properties under application. In both divisions the classification rests almost wholly on the quantity of vehicle present and not at all on the character of the pigment.

Although it is desirable that we should have good specifications for paste paints as well as for liquid paints, yet, inasmuch as the paste paints must in general be thinned down before use and in this process may be diverted into any one of several different subdivisions of the liquid paints, according to the character of the thinning liquid, it is only natural that the greater interest should center in the finished paints themselves, and it is these finished paints which not only command the greater interest but also present the greatest obstacles to standardization and specification.

EFFECT OF CHEMICAL REACTIVITY IN GRINDING

In theory the pigment of a paint is supposed to be essentially inert chemically, as regards the vehicle, the paint being a plain mechanical mixture of finely powdered pigment with a more or less viscous liquid. In the majority of paints, however, this condition is not immediately realized, because nearly all of the available vehicles contain organic acids in varying degree and kind, and many of the pigments are basic in character, some of them highly so. Under these circumstances a certain amount of chemical reactivity is to be expected, especially under the frictional heat of grinding. From the purely scientific standpoint this does not impair the validity of the theory, for if the new substances formed by the reaction are soluble in the remaining unaffected vehicle, then they become a part of the liquid phase, and if they are insoluble they become a part of the solid phase, so that finally we have a pigment and vehicle which can no longer react with each other. The important point to be considered here is that the resultant paint may, and generally does, have notably different properties from what it would have shown had there been no reaction; furthermore, sometimes these differences may be advantageous and at other times disadvantageous.

In most cases the pigment and vehicle are so chosen that the reactivity shall be relatively very small and fairly constant, but if not so chosen and if the reaction becomes extensive, either at once or during a considerable time, then the paint generally becomes useless, especially on storage. These, however, are not the only complications due to the pigment.

Aside from anything which may be traced directly to chemical reactivity the pigment may have a profound influence in other ways for which, up to the present, there is no tenable and comprehensive theory. Such influence may best be shown by citing illustrative cases.

A good raw linseed oil exposed in a thin film will dry in five or six days at ordinary room temperature. The same oil after the introduction of dryers may be made to dry in seven or eight hours under the same conditions; such an oil is readily obtainable commercially as "boiled" oil and in the trade is a fairly definite product. There are several hundred pigments in common use representing about forty or fifty different types or kinds which differ widely both chemically and physically. When these are ground into paste paints with either raw or boiled oil we notice that while the drying

time of the oil remains unchanged in some cases there are other cases in which it is accelerated and still others in which it is retarded. We shall quote only a few of the extreme cases.

MATERIALS WHICH ACCELERATE OR RETARD DRYING

Knowing, as we do, that small quantities of certain metals such as lead, manganese, cobalt, iron and a few others have a pronounced catalytic effect in accelerating the oxidation of oil, we are not particularly surprised to find that such pigments as white leads and umbers accelerate the drying speed, nor is it necessary to postulate anything further than a slight chemical reaction between pigment and vehicle to account for the acceleration. No such explanation, however, will account for the great retardation induced by such pigments as vandyke brown, various carbon blacks and certain coal-tar dye lakes made by precipitating basic dyes with tannin. It is difficult to imagine a pigment more inert chemically than the carbon black made by burning natural gas, and when ground in boiled oil it makes a good practicable paste with about 12 lb. of black to 88 lb. of oil. Good carbon black gives an ash of less than one-tenth of one per cent and contains occluded air sometimes to the extent of several per cent, but whether or not this occluded air is wholly displaced by oil in the ground paste, it is quite certain that any effect which either the air or the trace of mineral matter might have would be accelerative rather than retardant. Whatever might be expected as to the drying speed of such a paste paint, the fact is that twelve to fifteen days are required instead of the seven or eight *hours* required for the oil alone. If the drying time were retarded to only five or six days, it might be explained on the assumption that the metallic dryers are adsorbed by the finely divided carbon and their catalytic effect suppressed, but when the paint requires six or eight days more than raw oil itself, no such assumption is tenable. The different blacks owing their color to carbon do not all show the same degree of retardation, but no sort of chemical analysis reveals any sufficient reason for the observed differences. The most extreme case of retardation coming under the writer's notice was a "tannin-methyl violet" lake ground in raw oil; it did not dry in five months, and even when it could finally be touched was a gummy mess wholly unlike a good paint film. Fortunately lakes of this kind are unimportant, because better ones can be made, and at best they are too fugitive in color for general use, but the case is of considerable academic interest.

DURABILITY AND HIDING POWER OF PAINTS

Pigments also differ widely in their influence on the durability of paints made from them. This is especially important in exterior paints, or common outside house-paints well known and familiar to almost everybody. Whether this influence is a direct result of the same fundamental principle that affects the drying speed or not is open to question, but there is apparently some close connection, because long experience shows that some of those pigments which exhibit the greatest retardation also have the greatest influence in delaying the decay of the vehicle in service. Other factors probably enter, for it has long been known empirically that if small quantities of colored pigment be added to any given base white paint, the tinted paints so made will outwear the original white, and the hiding power is

also increased to a much greater extent than would be expected from such a small quantity of color.

A small instrument devised by Dr. Pfund of Johns Hopkins University allows us to measure this hiding power, and in a research bulletin issued from the laboratory of the New Jersey Zinc Co. on Aug. 1 of this year some results obtained by Dr. Pfund are set forth in detail. Among these results he shows that in a certain paint made from zinc oxide the addition of a very small quantity of lampblack raised the hiding power of the paint from 145 for the straight white to 486 for the light pearl gray tint, these figures expressing the hiding power in terms of square feet of black surface completely hidden by one gallon of paint. The proportion of lampblack required for such a tint is not more, and generally less, than one-tenth of one per cent on the zinc present—a quantity apparently out of all proportion to such a result. If any such demonstrable resistance to the passage of the visual rays of light follows the introduction of such small amounts of color, it is highly probable that the actinic rays are also obstructed and their influence in hastening the decay of the vehicle considerably diminished. This seems to be the most reasonable hypothesis, for it is fairly certain that actinism and water are the most potent causes of decay in exterior paints.

Whether paints be regarded as merely decorative or protective, or both, their durability as an economic factor is of paramount importance. No extended argument is necessary to carry conviction on this point for, on the average, it is fair to say that three dollars' worth of labor will be required to apply one dollar's worth of paint. The initial cost of the paint is to be considered, of course, but the real measure of value is the consumer's ultimate cost for continued upkeep, including the labor charges, and ultimate economy is clearly dependent upon the durability of the paint.

EFFECT DUE TO SIZE AND SHAPE OF PARTICLES

One other important influence of the pigment must be noted, and that is the effect due to the mere size and shape of the particles. Mixtures of pigments with any paint vehicle do not take on the physical properties characteristic of good paint until the particles present a relatively large specific surface to the liquid vehicle. Roughly speaking, the particle diameter may range from 0.2 micron to 50 microns with a mean average of 5 to 20 microns. When pigments are reduced by any process of mechanical grinding, the particles are far from uniform in size and if the material is subject to cleavage, the diameter in one direction may be much larger than in another, so that in stating average size we do not give a full idea of the physical state. It makes a great deal of difference whether there is a wide range between the maximum and minimum size, or whether the particles are more nearly uniform. The important point to us now is that as the particles become finer the tendency to flocculation increases, and, unless counteracted by the dispersive power of the vehicle, all sorts of changes in the consistency and applicability of the paint may ensue. However interesting the further discussion of this phase of the subject might be, we are concerned here only with the relation of such effects to the preparation of specifications, and enough has been said to show that they alone would render difficult the full description of a paint by merely specifying the ingredients and their proportions.

Whatever the difficulties arising from the pigment,

those arising from the vehicle are quite as great. There is no practical vehicle composed of a single unitary substance of fixed properties, and rarely if ever is the vehicle of a finished paint composed wholly of any one of the drying oils in its original state; almost invariably metallic dryers must be added, and while our knowledge of some of them is satisfactory, we know much less about those which have been prepared by the various cooking processes in common practice. Even linseed oil itself comes to the paint manufacturer in no fewer than five types—viz., raw, refined, boiled, bodied and blown—all in daily use, and when we consider the cooked and uncooked mixtures of the various drying oils with other substances whose chemistry is even less definitely known, we are forced to realize the essential hopelessness of attempting to describe them in terms of composition.

If then such obstacles to full specification by composition are interposed by both pigment and vehicle, what are we to do? The answer to this question is easy, but the preparation of a good specification founded on this answer is more difficult. If we consider paint from the consumer's standpoint the composition is of no great moment except in so far as the presence or absence of some particular ingredient positively adds to, or detracts from, the economic value of the paint. The consumer buys paint for what it will *do* and if he can rely upon a definite performance in service his further interest is perfunctory. We may write a good specification therefore by stating what the paint shall do, knowing of course that such a paint can be made, and the only real obstacle to this procedure is that we have no trustworthy test that will indicate with reasonable certainty the probable durability of the paint in service.

DURABILITY TESTS

Experience shows that the value of paint rests chiefly on five main properties—namely, color, degree of gloss, hiding power, working properties and durability, all physical attributes. All these, except durability, are susceptible of quantitative measurement, and if we could measure durability, we could determine the economic value of such paints without knowing anything about their composition.

When Committee D-1 first began its systematic study of paints it quite naturally attacked the problem from the chemical side on the reasonable assumption that if the composition were fixed the physical properties must also be fixed. Some of the reasons why such a method could be only partly successful have been given above in considerable detail. The committee soon realized that the subject was complicated, and in order to simplify matters confined its attention for some years chiefly to one type of white paints. On the Arlington test fence alone about 240 white paints were tested out in which the differences were due chiefly to changes in the proportions of the more common white pigments while the vehicle was maintained as nearly constant as possible. Supplementary tests of a similar kind were carried out, literally in thousands, by individual interests, but in spite of every care and an enormous amount of work, the knowledge derived has not been considered enough to serve for a satisfactory specification. The more recent efforts therefore have been directed more toward a study of the important physical properties, and the present tendency is to demand cer-

tain physical properties in a quantitative degree, putting up to the manufacturer the problem of how to get them in.

Specifying varnishes by composition has met with the same obstacles that pertain to paint. Until very recent times the attack has been from the chemical side despite the fact that our chemical knowledge of even the raw materials involved is incomplete, meager, and sometimes even no more than speculative. Varnish is simpler than paint in that there are no complications due to pigment, but when two problems are both beyond our capacity to solve, it makes little difference which is the more complex.

THE KAURI REDUCTION TEST FOR DURABILITY

During the war large quantities of varnish of maximum durability were required and there was great need for some test which would give some indication of the durability of the many brands offered. Under the stimulus of this pressure a method of test was developed from an idea that has been regarded as axiomatic in the varnish industry for generations. No gum-and-oil varnish yet made has anything like the durability of a first-class linseed oil paint in which the vehicle is practically all linseed oil with only the minimum proportion of dryers, and as the proportion of gum in varnish increases, the elasticity and durability are diminished. It has always been held that finishing varnishes which are required to withstand exterior exposure should always be "long in oil" and that elasticity and durability were accompanying features more or less in direct proportion. After thorough drying, short-oil varnishes crack readily when sharply bent, and therefore if we add more gum to a long-oil varnish until it cracks when bent we have a measure of the "length" of oil, and consequently the probable durability. This test is the so-called "Kauri Reduction Test" and for the detailed method of carrying it out we must refer you to the latest Inter-departmental specification for spar varnish. Whatever the further development of this test may show, it is founded on many years of solid experience, and while its results may not run exactly parallel to the service tests in all cases, yet as a test it is less liable to error than the service tests themselves unless the latter are carried out with most unusual care.

For some time yet it may still be desirable to include in varnish specifications the composition desired so far as that composition can be determined by analysis with reasonable accuracy, but by specifying what the varnish shall *do* and expressing it in terms which our present knowledge can measure quantitatively we are taking a long step ahead.

MUCH PROGRESS IN RECENT YEARS AND FUTURE FULL OF OPTIMISTIC EXPECTATIONS

During the past five or six years in which the attack has been active from the physical side much more progress has been made than in any previous similar period. Work is now under way which we hope will result in an accelerated test for durability in paints, and if this hope is realized the future is rosy with the optimistic expectation that, while we may not indeed reach the ideal, yet, for the first time in the history of the industry, we shall be able to standardize with reasonable accuracy the more important types of both paint and varnish, and write specifications which will be rational, sound and useful.

Brooklyn, N. Y.

Sidelights on the Chemical Exposition

General Impressions of an Interested Spectator and a Brief Account of Some of the New Products.
Apparatus and Materials Exhibited at the Seventh National Exposition of
the Chemical Industries, New York, Sept. 12 to 17

THERE were many new things to be seen at the chemical exposition this year and many old things were dolled up in new clothes and made to look attractive. It would have required weeks to inspect everything and to talk with all who were in charge of the many interesting exhibits. The writer of these brief notes is frank to admit that he didn't see everything. In fact there were a lot of important developments which he missed entirely and he probably wasted a good share of his time gossiping about inconsequential matters. However, he did observe many unusual things, and these notes were jotted down with the idea of conveying some of his impressions to those who were unfortunate enough to have missed the chemical show or were too occupied to make a detailed study of the novel products, apparatus and equipment. No effort has been made to arrange these items according to importance, novelty or interest and they are presented with an apology for their many errors of commission and omission.

THE DYE MAKERS were very much in evidence. The most elaborate architectural effort was doubtless the exhibit of the National Aniline & Chemical Co., although the booths of the Calco company, Klipstein and Sherwin-Williams were quite notable. The National's exhibit was one of a central group of the related corporations—Barrett Co., Solvay Process Co., and General Chemical Co.—and represented an old Egyptian street. For background on either side were the blank walls of the dwellings, interrupted here and there by doorways. At the street corners were four high ornamental pillars. All these structures and the partitions outlining their exhibits were painted in very harmonious blues, reds and yellows—rather soft and subdued as one would expect of colors generations old. The dooryards were shaded by more brilliant yellow awnings. The rumor that Sherwin-Williams was gradually giving up its coal-tar departments was completely refuted by a prominent array of new products, which included dyes for lake and ink manufacture and a new rubber accelerator known as formaniline. Attractive samples of fur, cloth, carpet and paper which had been dyed with these products gave an idea of the scope of this company's activities.

AN AIR OF DIGNITY and seriousness of purpose characterized the display of the Calco Chemical Co. The many new pharmaceuticals being developed for household and professional uses were given positions of prominence. Among these were calusol, a household antiseptic, and salicaine, a new local anæsthetic to take the place of cocaine.

KLIPSTEIN'S EXHIBIT was housed in a dazzling white pergola, with royal blue hangings for background—a colorful exhibit, much simpler in design than the

Egyptian street, but nevertheless extremely impressive. But with these few notable exceptions, the dyemakers' exhibits seemed less attractive than last year; perhaps that was because we were continuously meeting a party of dusky-skinned strangers, probably native of some country in southern Asia. One woman was draped in a magnificent shawl, of Oriental red, with a border vaguely suggesting the Paisleys dear to our grandmothers. Were the writer a dyemaker, he would try to make that red.

TWO OTHER BRIGHT SPOTS ON THE HORIZON were the colorful exhibits of the Newport Chemical Works and the Chemical Co. of America. The former now claims the distinction of having a very complete line of the famous vat colors of the indanthrene series. A number of new dyes have recently been added to this important series and as a result the number of products "not obtainable in the United States on reasonable terms as to price, quality and delivery" has been lessened.

A FEW BOOTHS, here and there, were vacant. Others seemed to be packing up, ready to go—but when you came closer, it proved that they were exhibits of trucks or other package-handling equipment. And speaking of packages, were you not struck with the number of booths which exhibited barrels, boxes, paper cartons and such like containers?

REVERTING TO VACANT BOOTHS, some were vacant and some were almost vacant. They suggested that the stingy hand of economy had intervened between the time when the space had been paid for and the construction of the exhibit. But still that explanation does not altogether fit the du Pont company. Last year everyone was greatly impressed by its magnificent purple hangings, reaching clear from ceiling to floor. And where was the collection of notable machinery which has featured the Buffalo Foundry & Machine Co.'s space in every exhibition since the first, and has almost become an institution?

THERE IS AT LEAST ONE COMPANY which keeps its chemists at work when dull times come and sales fall off. As a result it has developed a new product which promises to revolutionize gas engine manufacture. We refer to Dowmetal and its use for the piston heads of internal-combustion motors. As a conductor of heat it is three times as effective as cast iron and because of its lighter weight, engines can be speeded up to give more power with less strain. They don't generally boast of the fact, but the winning cars in the Indianapolis races were equipped with Dowmetal pistons. While the writer was discussing these things with Mr. Dow a man walked into the booth and, approaching the learned president of the Dow company, asked him if there was anybody there who understood chemistry.

With a whimsical smile Mr. Dow pointed to one of his associates near by who, he thought, might be able to talk with him. To ask this former professor of chemistry and toxicology if anybody around there knew any chemistry seemed funny, but the question would not down, whether it would be funny or sad to ask the presidents of many of our chemical corporations whether they knew any chemistry or not.

ONE OF THE REALLY NEW THINGS that attracted genuine interest was a new gyroballistic crusher that simply eats up the rock. The Stimpson Equipment Co. introduced several years ago the Mitchell screen, whose vibrating motion is caused by the very rapid vibration of a slightly balanced electric motor. The same kind of prime mover has now been applied to the top end of a crusher shaft with astonishing results. An entirely new principle is applied to crushing, wherein a force formerly considered destructive (vibration) is used constructively to produce an action of a cracking rather than crushing nature. The power requirement of the new machine is a paradox in that it is less while the apparatus is crushing than when it is operating without a load.

A MORE ELEGANT-LOOKING APPLIANCE is the new gas governor, designed by the Koppers Co., and primarily intended to regulate the pressure in the byproduct coke oven, thus preventing wastage of rich distillate from the coking coal through the brickwork, or the in-breathing of waste gas from the flues. Each battery of ovens has one of these governors operating a butterfly valve in the suction main leading to the recovery apparatus. As the pressure in the retorts goes up, from any cause, a float is raised which is connected by suitable linkwork to a pilot valve. The latter controls the flow of a body of circulating oil, allowing some of it to enter certain cylinders, whose rising pistons open the butterfly valve sufficiently to bring the gas pressure back where it belongs.

TO CATCH THE FEMININE EYE—and it did effectively—not a few exhibitors showed how their products entered into household utensils and furnishings. Many observers probably never before realized that applied chemistry is vitally necessary for their comforts. Lacquered, enameled and plated ware of all kinds were attractively exhibited; glassware and porcelains, and cooking utensils of aluminum, copper and nickel competed to catch the eye.

IF THE PROMINENT METALLURGICAL COMPANIES would collectively exhibit, it would make a metallurgical exhibition of considerable proportions. New Jersey Zinc Co. had a beautiful booth in blue and white, a background most effective for the silvery brightness of most of its articles on show. Other observers might offer first prize to the Nichols Copper Co. Its booth appeared to be the facade of a Greek temple, severe in the extreme. Directly in front was a large pedestaled fruit bowl made of sparkling crystals of blue vitriol. It was heaped with luscious fruit; a veritable altar to Demeter.

ANACONDA COPPER MINING Co. is to be especially complimented for a well-designed and harmonious exhibit. Not only was there an adequate showing of the several metals the company produces in bulk and various

byproducts, but there were also many specimens of chemical apparatus made of copper or copper alloys. Several manufacturers of copper utensils co-operated in this effort, contributing excellent panels or cases. For instance Duparquet, Huot and Moneuse loaned a very interesting collection of copper kettles and jelly molds, while Manning-Bowman's case of polished trays and percolators was particularly striking.

A NEW FORM OF DUCTILE NICKEL about which we have published several papers was exhibited by the British-America Nickel Corporation. A mammoth cathode, 20 ft. long, 5 ft. wide and $\frac{1}{8}$ in. thick and weighing 400 lb. was of especial interest, as was the company's statement that it is equipped to produce fifty such cathodes at one time. The new product was the result of five years' work in the laboratory of Mr. Madsen, for whom the metal has been named.

AS WAS SAID BEFORE, the du Pont company did not bring any of its many products to the exposition. The man at the desk labeled "Dyestuff Department," however, informed the writer that the company is now ready to announce the arrival of the Naphthol series of fast reds, scarlets, oranges, blues and pinks. These are the famous Naphthol AS colors introduced by the Griesheim works shortly before the war and their production in this country fills one of the last remaining gaps in fast colors for cotton.

"CANADIAN PACIFIC RAILWAY Co.—Exhibiting a colored map showing the industrial resources of Canada." This bare statement contained in the program certainly raised no great expectations. But the map was no ordinary colored map. It was a huge white thing; perhaps 20 ft. long and half as high, with a few sketchy outlines in black. In front was a switchboard. If you wished to see the route of one of the great railroad systems, merely press an appropriate button, and immediately flashed up a continuous line of miniature light bulbs; the names of the principal cities en route were also illuminated. Or if you wanted to know where Canada's precious metals were mined, push another one of the score of buttons and tiny red lights glittered here and there—Yukon, Rossland, Porcupine and dozens of others sprang forth. A regular Aladdin's map!

THAT PROMISING YOUNG OFFSHOOT of the Davison company, the Silica Gel Corporation, exhibited apparatus showing some important industrial uses for silica gel. For instance, in the Gayley process the gel is used to reduce the moisture in the blast for iron furnaces without refrigeration. The moisture content is brought down to $\frac{1}{2}$ grain per cu.ft. Adsorption from the gas phase is the basis for important uses of silica gel in refrigeration and in the manufacture of sulphuric acid by the lead chamber process. Removal of sulphur compounds from Mexican petroleum and the refining of various petroleum distillates by means of this gel depend upon its properties of adsorption from the liquid phase. Silica gel will adsorb 18 to 20 per cent of its weight of these offensive smelling compounds, and furthermore the gel can easily be repurified.

A NEW ROLLER PUMP which is as simple as rollin' off a log is the description given to the latest novelty of the Dorr Co. The pump is for any fluid or mud that can be passed through rubber tubing. The lower end

of the rubber tube is placed into the material to be pumped, and adjoining the pipe is a hard plane surface. A wheel (or spider) with three or more rollers attached at the periphery is also immersed on the other side of the pipe opposite the plane surface. Then, when the spider revolves, the first roller squeezes the pipe and pushes up some of the fluid, while before the first roller has been withdrawn the second has begun to squeeze upward, and so with the third, until a continuous stream is on its way—a sort of peristaltic motion applied to pumping.

NOW THAT p_{H} HAS COME SO VERY MUCH IN VOGUE, considerable attention has been attracted by the Elliot ionometer, which appears to be a rough and ready instrument adapted for rapid work and factory control. The Will Corporation declared that it is of especial service where dark solutions prevent the use of ordinary indicators.

A NEW SODA FOUNTAIN DRINK called "Cheerio" was dispensed to all comers at the booth of Heyden Chemical Co. Whether the great "heart" of the American public will take to it as it has taken to "Coca-Cola" or whether it will adopt the new synthetic grape juice of the Florasynth Laboratories, remains to be seen.

AN IMPORTANT INNOVATION in chemical engineering construction may follow the development of 3-in. Pyrex glass pipe-lines with T and L connections to be used as a substitute for brass pipes. The installation in tanneries for handling tanning liquors suggests important uses in other chemical industries.

SAMPLES OF A METAL which has some of the characteristics of bronze, but contains neither lead nor tin, were distributed in the form of little chisels by the American Metal Products Co. The alloy is made of copper, steel, aluminum and one other metal in varying proportions to serve different purposes, with copper preponderating. We suggest that this be called hardened copper, so that when gifted inventors come around with the secret of the lost art of hardening copper for sale for a million dollars, they may be told that it is done already.

ONE OF THE REASONS FOR THE CROWD which constantly surrounded the exhibits of the Bureau of Standards was the fact that many features were being carefully explained by the men who were responsible for the inventions and discoveries. For example, C. O. Fairchild showed the results of his process for the fusion of optical glass cells and similar articles which cannot be molded because of interference with optical properties. Formerly these were cemented and the cement was often a source of trouble. A small sample of the platinum developed by Dr. Edward Wichers was shown. The fact that it is spectroscopically free from any impurities suggests the possibility of greatly increasing the utility of rare-earth and resistance thermocouples. Priest's spectrophotometer is of such convenient operation that it may prove of great service in the much-needed work on the standardization of coal-tar dyes.

AFTER A VISIT to the booth of the Lake Erie Chemical Works of the General Electric Co., it is not difficult to predict that hydrofluoric acid will soon be displaced

in the production of frosted effects on glass. With Permelsol, a colloidal suspension of a mixture of inorganic compounds, similar results can be obtained more easily and at less expense. The mixture is simply sprayed on with an air brush and then fixed by development in a chemical bath. The finish may be colored if desired by the use of inorganic pigments. Another advantage claimed for this method is that it eliminates the breakage which occurs when it is attempted to fix frosting enamels on glass surfaces by baking.

IT MUST BE ALMOST LIKE SPLITTING HAIRS to manufacture an 840-mesh wire cloth, and it is no wonder that A. A. Campbell of the Newark Wire Cloth Co. felt himself called upon to design a special microscope for accurately measuring such fine mesh. By the use of a special micrometer stage this unique instrument measures accurately to one one-hundred-thousandth of an inch and it is claimed that with a vernier scale the accuracy was extended to one millionth of an inch. Although Mr. Campbell's device was built to serve a special purpose, it would appear that it might find important application in many other industries.

DOWN SOUTH THE LUMBER AND NAVAL STORES INDUSTRIES have for years been destroying yellow pine trees with such reckless abandon that less than one-third of the tree ever reaches the market in the form of lumber, lath or shingles. The stumps are left in the ground, for the enormous cost of removing them has in the past made it impracticable to reclaim the land. Chemical engineering has now appeared on the scene and pulp and wrapping paper and many byproducts, such as turpentine, pine oil and rosin, are being recovered. One of the pioneers in this field is Joseph Wallace & Co., which company demonstrated some of its accomplishments at the exposition.

A NUMBER OF THE SCIENTIFIC SOCIETIES AND TRADE ASSOCIATIONS took advantage of the educational opportunities offered by the exposition and used their booths to disseminate information to the general public regarding the scope of their activities and the possibilities for progress in their particular fields. These booths also proved convenient meeting places for members and were the scenes of many interesting reunions. Prominent among the society booths were those of the American Chemical Society, American Ceramic Society, American Electrochemical Society, Society of the Chemical Industry and the New Jersey Chemical Society.

IS THERE A CHEMIST who could spend fifteen minutes in the booth of the National Lime Association and not come away with an overwhelming realization of his ignorance on the subject of lime and its uses? On a pyramid in the center of the booth were arranged samples of 120 products which require the use of lime at some stage in their manufacture. A large chart detailed the uses of lime according to industry and according to function. Lime manufacture was visualized by a clever mechanical model of a lime plant, a flow sheet of the process, a chart giving the chemical engineering data involved, and photographs of typical plants. A feature of popular interest was a flashing red light which indicated the rate of consumption of lime in the United States—one ton every $2\frac{1}{2}$ seconds.

Meeting of the Fertilizer Division, American Chemical Society

THE fall meeting in New York of the Division of Fertilizer Chemistry was held Wednesday and Thursday, Sept. 7 and 8, 1921, under the chairmanship of F. B. Carpenter. H. C. Moore was secretary.

The only discussion of phosphate supplies on the program was a report by Waggaman on the briquetting and use of Florida and Tennessee phosphate rock for manufacture of phosphoric acid. Full details have been given by him in *CHEMICAL & METALLURGICAL ENGINEERING* (Dec. 1, 1920, p. 1057, and Sept. 14, 1921, p. 517).

CYANAMIDE IN SOME FERTILIZER MIXERS

Cyanamide as a fertilizer material was defended by W. S. Landis, who presented an elaborate reply to the article by Harger, which was given at the Chicago meeting of the division last fall. Both ton-lot and laboratory-scale tests were reported to show that in the quantities recommended the cyanamide does not form dicyanodiamide, a plant poison, in objectionable amounts "when it has been properly incorporated in the mixture." By analysis of the mixtures thus prepared it was attempted to identify the condition of all the added nitrogen, but from 15 to 50 per cent could not be found by the methods used. It was believed that only negligible percentages remained as dicyandiamide, the major part being as amino acids, guano-urea and urea.

J. E. Breckenridge reported also on cyanamide fertilizer experiments with the output of the American Agricultural Chemical Co., in which the Bureau of Soils co-operated. Tests of mixtures containing 40 lb. per ton of cyanamide show these to be safe from toxic plant materials.

Discussion by Harger and Schreiner of the Bureau of Plant Industry made clear their desire not to criticize the use of small amounts of cyanamide as is now trade practice, but their objection to the conclusions drawn by Landis according to the analytical methods which he used. It was also stated that Harger's work was the first presentation of the facts regarding the important influence of acid phosphate on the reaction by which the polymerization of cyanamide takes place.

WOOL SCOURING WASTES FOR FERTILIZER PURPOSES

Wool scouring wastes for fertilizer use offer promise if the U. S. Department of Agriculture results presented by F. P. Veitch can be realized in practice through co-operation of wool and fertilizer interests. The 300,000 tons of unscoured wool used annually in the United States averages 4 per cent K_2O , 0.5 per cent N and 15 per cent grease, with the first two named in useful water-soluble forms. The "concentrates" mix well with other materials and appear otherwise good.

GREENSAND AS A SOURCE OF FERTILIZER POTASH

Potash from greensand as a commercial proposition was discussed at length by R. N. Shreve, who presented figures as to the plant to use this method on 1,000 tons per day of greensand. This plant will make KNO_3 and caustic soda by treating the sand with lime at 470 deg. F. in the presence of $NaNO_3$. The byproduct caustic made will be 40 tons $NaOH$ per 100 tons KNO_3 , thus justifying use of $NaNO_3$ instead of $NaCl$ in the reaction, for most if not all of the expected output of 20,000 tons K_2O equivalent per year. The solid residue

from the process will be used for brick manufacture and special potash salts.

OTHER PAPERS PRESENTED

The use of triangular co-ordinates was cleverly described by Oswald Schreiner in explaining methods and interpretation of results in field use of three component fertilizers. The failure of many experiments to indicate the action of commonly used fertilizers—e.g., high potash for potatoes—was shown.

L. S. Bushnell emphasized a similar problem and use of similar methods in discussing the limiting constituents in fertilizer effects.

The soil and plant problems were covered also by J. J. Skinner's and H. A. Noyes' reports.

Analytical methods for nitrogen determination were on the program in papers by Charles S. Cathcart, J. E. Breckenridge, R. N. Brackett, H. C. Moore. Other analytical problems were covered by R. McG. Shuey, C. G. Atwater, Paul Rudnick and C. S. Robinson.

Meeting of the Rubber Division, American Chemical Society

THE fall meeting in New York of the Rubber Division, American Chemical Society, was held Wednesday and Thursday, Sept. 7 and 8, 1921.

In the beginning the Rubber Division was more or less of an experiment. Even its strongest supporters were dubious as to the outcome. Two years have now passed since its inception. Five meetings with steadily increasing interest have been held. There are over two hundred members, and finances are in excellent condition. In the beginning it was difficult to get the members to express their opinions, but at the meeting this year it was difficult to keep to schedule, so many had ideas which they wished to present. Without the least exaggeration it can be said that America's rubber technologists got together on a common basis for a full and free discussion of fundamental problems.

It was this spirit that prompted the division to pass unanimously a resolution calling the attention of the Rubber Association of America to the need of co-operative research for further investigation of the fundamentals of the industry.

With but one important exception, every American company interested in rubber has contributed something during these two years. One company, however, which is exceedingly well equipped, has so far declined to take anything but a selfish aspect of the situation. Thus far its organization has contributed nothing, and is apparently proud of it.

Election of officers took place at the close of the Thursday morning session. In recognition of his excellent contributions on the subject of acceleration, the division chose C. W. Bedford, of the Goodyear Research Laboratories, for chairman, to succeed W. W. Evans, of Goodrich, retiring. Arnold H. Smith, of the Thermoid Rubber Co., of Trenton, was re-elected secretary.

MECHANISM OF THE ACTION OF ZINC COMPOUNDS

C. W. Bedford and L. B. Sebrell presented the fourth part of their study on the Reactions of Accelerators During Vulcanization. This paper was by far the most important contribution to the chemistry of rubber presented in the two years the Rubber Division has been in existence. An abstract cannot do it justice.

Zinc oxide enters into chemical combination with the accelerators it activates and produces zinc salts which are much more powerful.

Zinc higher sulphides were described, which produce vulcanization in a manner similar to antimony sulphide.

The authors found that if H_2S and SO_2 are passed into cooled benzene and then one of the gases is run in for a time after the other is shut off, a form of sulphur thiozone, is produced, which when stirred into a rubber cement brings about vulcanization with setting of the cement in about 40 minutes at room temperature. This is evidently the key to vulcanization by the Dubosc-Peachey process.

MINERAL RUBBER

C. Olin North presented a paper on mineral rubber. This paper contained the most thorough inquiry into the effect of a compounding ingredient on rubber that has appeared to date. Mineral rubber is prepared by blending gilsonite and natural or blown asphaltic still residue. Various tests, such as stress-strain relations, hysteresis, permanent set, abrasion and elongation under constant load, were made with stocks containing an increasing volume ratio of mineral rubber. From 7 to 10 volumes of mineral rubber per 100 volumes of rubber were found most advantageous.

THE TETRA-HYDROPHENYL DERIVATIVE OF RUBBER AND ITS TETRA-METHYL ETHER

Harry L. Fisher and Harold Gray presented a paper on tetra-hydrophenyl derivative of rubber and its tetra-methyl ether. Some old work of Weber's was repeated and a previous error corrected. When rubber tetrabromide is treated with phenol, hydrobromic acid is split off and a product having the following formula is produced:

This is soluble in caustic soda solution with the formation of the sodium salt. When this solution is treated with dimethyl sulphate the tetramethyl ether

is produced. These compounds may serve to determine the molecular weight of rubber.

CORRECTED STRAIN CURVES FOR RUBBER

J. W. Shields presented a paper on corrected strain curves for rubber. The author corrects the stress-strain curve for decrease in cross-section area. In other words, he draws the true curve based on the actual area of each increase of load and a curve without the familiar S hook is obtained. It is similar to that obtained for other materials. Hooke's law holds for such curves which have the equation:

$$S = CE + \left(\frac{e}{B}\right) \times \frac{1}{K}$$

S = stress corrected for decrease in cross-section area.

e = elongation in per cent divided by 100.

E = Young's modulus.

C , B and K are constants.

The equation is said to apply to a wide variety of curves.

THE DETERMINATION OF PARTICLE SIZE OF PIGMENTS

W. W. Vogt presented a paper on the determination of the particle size of pigments. A rapid method for testing the average size of particle of various pig-

ments was described. The author prepares a suspension of pigment in liquid. Castor oil and carbon tetrachloride or glycerine and water may be used, depending on the nature of the pigment. The suspension is placed in a Nessler tube and the height of column adjusted so that the wires of a tungsten lamp placed underneath cannot be seen. The volume of filler necessary to obscure the area of the bottom of the Nessler is calculated to sq.cm. per c.c. of material and is known as the obscuring power. The method is said to be excellent in checking relative size of the same pigment.

RUBBER RESEARCH AND RUBBER TESTING

O. de Vries presented a paper on the preparation and testing of crude rubber.

Dr. de Vries is the director of the Dutch Experiment Station of Java. His visit to this country is for the purpose of ascertaining the direction research on rubber should take. He pointed out that much of their work on regulating the uniformity of rubber in cure and other properties is apparently without value to the American consumer. He wants to produce a better rubber and has compiled a set of questions which will be mailed the members of the division by the secretary within a short time.

Appearance of crude rubber is no guarantee of its inner properties, such as its rate of cure, tensile, etc. Resting trees slows down the rate of cure. Smoked sheets mill better than pale crêpe.

In the discussion, W. B. Weigand presented a method for arriving at relative plasticity. A square sheet is cut off the mill, and the crawl or contraction noted.

OTHER PAPERS PRESENTED

The Microscopy of Rubber Fillers: By Irene C. Diner.—This paper is preliminary to work on analysis of rubber compounds by use of petrographic methods. Optical constants and the effects of single and double polarized light for several of the more common fillers were described.

The Use of the Microscope and Photomicrographs in the Study of Inorganic Materials Used in Rubber: By Benton Dales and W. W. Evans.—Various fillers were dispersed in a 5 per cent rubber cement. Slides were prepared by floating them on the cement, after which the films were vulcanized by sulphur chloride. By loosening one end from the glass the thin film could be placed under any desired strain and its effects noted.

Recent Developments in the Art of Rubber Microsectioning: By Henry Green.—Previous methods described by the author required the use of liquid air and liquid CO_2 for freezing the sections before using the microtome. Liquid air is not accessible to all. Mr. Green has worked out a method whereby the sample is badly overvulcanized in sulphur chloride, after which it can be sliced as easily as if it were frozen.

Rapid and Low-Temperature Vulcanization: By G. S. Whitby and A. H. Smith.—Experiments with piperidine-piperidyl-di-thio-carbamate were described. Previous work by Whitby without an activator was repeated but in the presence of zinc oxide. The rate of cure was greatly increased. This is a very powerful accelerator.

An Improved Oven for Accelerated Aging of Rubber: By C. W. Sanderson.—A small oven mounted in an oil bath for accurately maintaining temperatures while dry preheated air is passed through was described.

An Apparatus and Method for Abrasion Tests on

Rubber Compounds: By J. C. Sproull and W. W. Evans. Test-pieces are mounted on a shaft which is revolved in carborundum dust. Abrasion values which are comparable to road tests were said to be obtained by the use of this apparatus.

The Determination of True Free Sulphur and True Coefficient of Vulcanization in Vulcanized Rubber, II: By W. J. Kelly.—An extension of work already published. The author eliminates sulphur combined with pigments, resins and proteins. This work had to do with stocks containing zinc oxide, hexamethylene tetramine, etc.

The Solubility of Sulphur in Rubber: By C. S. Venable and C. D. Green.—Solubility of sulphur at 55, 75 and 95 deg. C. investigated. The solubility increases with temperature, and with increase in coefficient of vulcanization.

Determining Temperatures in Tires.—A simple method for determining temperatures in tires was described by Frank G. Breyer. An awl with a hole bored through the head is used as a needle. The hot junction of the thermocouple is inserted in the hole in the awl. The couple is put in place by merely sticking the awl into the tire and withdrawing it. Mr. Breyer offered to supply the rubber trade with these awls and tested thermocouples at a very reasonable figure. He also mentioned that his company (New Jersey Zinc Co.) would supply those who are studying mechanism of vulcanization, acceleration, etc., with chemically pure zinc oxide.

GENERAL DISCUSSIONS

General discussions were held on: Accelerated Aging Tests, Mechanism of the Vulcanization of Rubber, Methods of Plotting Physical Testing Data.

Accelerated Aging Tests: Led by W. W. Evans.—The recently published article by W. C. Geer and W. W. Evans on "Ten Years' Experience With Accelerated Aging Tests" was discussed. There was a wide divergence of opinion as to temperature and other conditions of test, and also as to the actual value of such tests. The majority favored 70 deg. C. and circulation of air. An interesting test was described by A. A. Somerville. Test pieces are placed in a Mason jar and immersed in boiling water. During the first stages of the test oxidation is a factor. Later the oxygen disappears and the effect of heat alone is noted.

The Mechanism of Vulcanization of Rubber: Remarks by C. W. Bedford, G. D. Kratz, P. I. Murrill and others may be summarized in the statement that vulcanization is brought about by the action of sulphur carriers which are usually polysulphides. The carrier adds on sulphur, reacts with rubber, is split off, leaving the sulphur attached to the rubber. The process is repeated until there is no more sulphur or the temperature drops below the point where the reaction is possible.

Methods of Plotting Physical Testing Data: Led by W. W. Vogt.—An extremely simple and convenient method of visualizing and comparing the data contained in several stress-strain curves was presented. Load is plotted on the Y axis and time of cure or volume of filler on the X axis. The loads necessary to produce 100, 200, 300, etc., per cent elongation for the various stocks are plotted, and smooth curves are drawn. The method has the advantage that there is no overlapping of curves on the chart, and yet all points of interest are unobscured.

Capacity of Electrolytic Zinc Plants

At the present time the potential aggregate production of electrolytic zinc for the world amounts to approximately 125,000 tons, or 250,000,000 lb., per year. This is divided about as follows:

	Tons
Anaconda Copper Mining Co., Great Falls..	55,000 to 60,000
Consolidated Mining & Smelting Co., Trail..	20,000 to 25,000
Electrolytic Zinc Co. of Australasia.....	30,000 to 40,000
Judge Mining & Smelting Co., Park City....	2,500
Brunner, Mond & Co., England.....	1,700

The record production for Anaconda's plant was made in July, 1920, when a total of 11,801,662 lb. of cathodes was drawn. For Great Falls conditions this does not all represent marketable zinc, inasmuch as about 8 per cent of the cathode production must be blown into zinc dust for removal of copper and cadmium from the solutions. It should be borne in mind, however, that if the Great Falls plant had a copper-free concentrate to treat this would have very nearly represented net production, as on such concentrates probably not over 15 per cent as much zinc dust would have been required for purification. While, therefore, the Great Falls Plant is rated at only about 110,000,000 lb. per annum, this means production from the relatively impure and cupreous concentrates on which it operates. The maximum output of the tank house has been demonstrated to be at the rate of 140,000,000 lb. per year, or 193 tons per day, and it is probable that under favorable conditions, operating on concentrates such as are produced in the Joplin districts, the equipment at Great Falls could roast, leach and electrolyze sufficient concentrate for a production of 200 tons of zinc per day.

Casein Glues Exceptionally Durable in Damp Places*

Casein glues are as a class more water-resistant than animal and vegetable glues, but they are not, strictly speaking, waterproof. There is no glue that is waterproof in the sense that it is absolutely unaffected by water after a long immersion. Nevertheless there are casein glues that are so water-resistant that plywood glued with them will withstand soaking for many weeks in water or exposure for many months to a warm, damp atmosphere. Under similar conditions animal and vegetable glues would soon lose their strength.

When casein glue joints are kept fairly dry, they can be expected to retain their strength and remain unchanged for an indefinite period, as is the case with animal and vegetable glues. Water-resistant casein glue in a joint, kept constantly wet, will after a long time weaken, but it will ordinarily regain a great deal of its strength if the joint is dried. In a study aimed to discover the reason why casein glues ultimately decompose when kept moist, it was found that under certain conditions the decomposition seemed to be due to a hydrolysis of the casein, undoubtedly brought about by the sodium hydroxide always present in casein glues.

This explanation has been misunderstood to some extent. It should not be taken to mean that casein glues are unreliable and not durable enough for use in manufacturing plywood and other glued products. On the contrary, casein glues are considered as permanent as any under dry conditions, and the water-resistant casein glues are more permanent than animal or vegetable glues under wet or damp conditions.

Calculation of Equilibrium in Metallurgical Reactions

Thermochemical Computations Much Used by Physical Chemists, but Relatively Unknown to Metallurgists, Are Applied to Important Furnace Reactions — Relative Stability, Danger of Oxidation, Ease of Reduction, and Equilibrium Conditions Can Be Inferred From Thermal Data

By PAUL D. MERICA

METALLURGISTS are not infrequently called upon to answer questions concerning the nature of chemical reactions occurring in the various processes of smelting or refining in which they are interested and the extent to which and direction in which these reactions are influenced by change of temperature or by the addition of other materials either in the solid, liquid or gaseous form. In answering such questions recourse may often be had to the results of experience in plant operation or of direct experimentation with the reactions in question, and upon these concrete facts may of course be built the soundest and most satisfactory answer. Often, however, our experience may not be in such form as to be exactly applicable to the particular problem and we must resort to other more general and theoretical considerations for a solution of it.

WHAT REACTION WILL OCCUR

Will a certain chemical reaction proceed readily at a temperature of 1,500 deg. F.? A well-known rough and ready aid to the chemist or metallurgist in answering such a question is the consideration of the heat of reaction, it being assumed that if the reaction is accompanied by evolution of heat it will proceed, but that if accompanied by absorption of heat it will not. The heat of reaction may be readily calculated from the heats of formation of the compounds entering into it, data which are available in Richards' "Metallurgical Calculations" and Liddell's "Metallurgists' and Chemists' Handbook." It is perhaps also well known that considerations of this sort will lead often to entirely incorrect conclusions, particularly in the case of reactions involving gases and proceeding at high temperatures—reactions in which the metallurgist is peculiarly interested. The use of this simple criterion for deciding whether a reaction will or will not proceed must be restricted to the case of reactions involving only pure solids and liquids other than solutions—i.e., the so-called condensed systems, but in such cases gives conclusions not far from the truth in the majority of cases.

Modern developments of theoretical chemistry have shown the existence of further relations which we may utilize to extend somewhat our powers of theoretical prediction, and it is the purpose of this paper to describe and illustrate the use of methods based upon these relations and to show what are their scope and limitations and upon what fundamental laws and hypotheses they are based. For although the utilization of these methods has become somewhat familiar to the physical chemist, it does not appear that their value has become apparent to metallurgists in general or that any description of them has been given in metallurgical literature. It is therefore with the excuse of making these methods available to metallur-

gists that the author ventures to set down the discussion which follows, much of which, including the fundamental theory, is not new or original with him. He has himself found them of definite, practical value and does not doubt that they can be as valuable to others.

One fact must be emphasized at the very outset—namely, that the discussion to follow deals entirely with the equilibrium of chemical reactions and is based upon simple thermodynamic laws modified by a few assumptions. Results of such calculations of chemical reactions as are described will enable one to make definite predictions whether a chemical reaction should proceed in a certain direction or in which direction it will proceed if any chemical change takes place, but it will not enable one necessarily to predict whether a reaction which *should* proceed *will* proceed. It is a familiar fact that many reactions which should go on in a certain way according to their affinities will not do so owing to lack of mobility or velocity of the molecules or to other as yet little understood reasons. For example, hydrogen and oxygen will not unite at ordinary temperatures to form water with measurable velocity, although water is more stable than a mixture of its two component gases. Generally speaking, an increase of temperature relieves this frictional effect or resistance to reaction, probably by increasing the vibrational or translational velocity of the molecules, so that metallurgical reactions at high temperatures usually proceed to the chemical or thermodynamic equilibrium with which this discussion is concerned.

THE AFFINITY OF CHEMICAL REACTIONS

The amount of free energy—available as mechanical or electrical energy—which may be obtained from isothermal, reversible execution of a chemical reaction between molar amounts of the reacting substances is the exact measure of the affinity of that reaction and may be considered identical with it. It may be measured in calories, watts or foot-pounds; if it is positive—i.e., corresponding to evolution of free energy—the reaction should proceed; if negative, the reverse reaction should proceed; if it is zero, the reacting substances are in equilibrium and no chemical change will take place. The affinity of a reaction is not equal, generally speaking, to its heat of reaction; these two quantities are connected by the following relation based alone upon the two laws of thermodynamics:

$$A - Q = T \frac{dA}{dT} \quad 1$$

where

- A = the affinity or free energy of the reaction.
- Q = the heat of the reaction.
- T = the absolute temperature.

$\frac{dA}{dT_r}$ = the derivative of A to T at constant volume.

It is evident that unless $\frac{dA}{dT_r}$ is zero the free energy cannot be equal to the heat of reaction, but may be either greater or less than it.

Now our handbooks do not contain experimentally determined values of the free energy or affinity of reactions and only to a limited extent are such values to be found in our chemical literature. The principal reason is that they are difficult to determine directly. Handbooks do, however, contain extensive data on the heats of formation of chemical compounds from which heats of reaction Q may easily be computed. If we were able to calculate the value of the right-hand term of equation 1 we could always compute from the known heats of reaction the free energies or affinities of chemical reactions and our task of attempting to predict the course of these reactions would be completed.

The most promising method of making this calculation appears to be that based upon an assumption first made and discussed by Nernst,¹ of which the direct statement here would mean little and is omitted. It is sufficient to say that although the assumption has only a limited theoretical basis, it has been quite thoroughly tested out in comparison with the direct results of experience and observation in various and widely different fields and appears to have established itself as a reasonably accurate hypothesis.

Upon the basis of equation 1 and this assumption A and Q may be shown to have the following relation:

$$Q = Q_0 + \Sigma bT^2 + \Sigma cT^3 + \dots \quad (2)$$

$$A = Q_0 - \Sigma bT^2 - \Sigma cT^3 - \dots \quad (3)$$

where

Q = the molar heat of reaction at constant volume at the absolute temperature T , considered positive if heat is evolved in the reaction. Q_0 , the same at absolute zero.

A = the molar free energy or affinity of the reaction at the same temperature considered in the same sense.

Σ = summation of reacting mols (considered positive) and resultant mols (considered negative).

b and c = coefficients depending upon the change of the specific heats of the reacting compounds with temperature.

From Kirchoff's law and equation 2

$$\Sigma S_T = \frac{dQ}{dT} = 2\Sigma bT + 3\Sigma cT^2 + \dots \quad (4)$$

where S_T = the true molar heat of each compound at the absolute temperature T and constant volume.

These liquids hold only for the case that pure solids and liquids (no solutions) alone take part in the reaction. It is seen that to compute values of A , the affinity, it requires only a knowledge of the heat of reaction at any temperature together with the values of the specific or molar heats of the reacting and resulting compounds at the same or several temperatures. The latter data are also available in reference and handbooks, although not as extensive as those on heats of formation.

Metallurgical reactions involving only pure solids and liquids are rare, but the following examples may serve to illustrate the application of the above equations.

Reduction of silver sulphide by mercury is supposed to proceed in amalgamation by the Washoe process.

molar heat of $\text{Ag}_2\text{S} = 248 \times 0.0746 = 18.5$

$$\text{Hg} = 200 \times 0.033 = \frac{6.6}{25.1}$$

$$\text{HgS} = 232 \times 0.0512 = 11.9$$

$$2\text{Ag} = 2 \times 108 \times 0.056 = \frac{12.1}{24.0}$$

If terms in T^2 , T^3 . . . be neglected, equation 4 becomes

$$\Sigma S_T = 2\Sigma bT$$

$$\text{whence} \quad \Sigma b = \frac{\Sigma S_T}{2T}$$

and for the reaction 5 at ordinary temperature

$$\Sigma b = \frac{25.1 - 24.0}{2 \times 300} = + \frac{1.1}{600} = + 0.0018$$

Substituting in 2

$$7,600 = Q_0 + 0.0018 \times 300 \times 300$$

$$Q_0 = 7,438$$

Hence, from 3

$$A = 7,438 - 0.0018 T^2$$

The affinity of this reaction is positive, but its value decreases with increasing temperature.

Again, consider the reaction

$$\Sigma b = \frac{12.16 + 6.67 - 6.4 - 11.9}{2 \times 300} = + 0.001$$

$$3,800 = Q_0 + 0.001 \times 300^2 \quad Q_0 = 3,710$$

therefore $A = 3,710 - 0.001T^2$

It is seen that the values of A for these reactions differ but little from those of Q , which is generally the case in reactions involving no gases or solutions. For this reason it is generally sufficient in such cases to consider only the heat of reaction as indicating sufficiently accurately the affinity of the reaction.

GAS REACTIONS

Most metallurgical reactions involve gases and it is to such reactions that the following methods of calculation are particularly applicable. Equilibrium in chemical reactions in which gases take part may be described completely, as is well known, by a statement of the equilibrium pressures of the several gases which are required to maintain the reacting system without chemical change. "The intensity of an action varies as the concentration of the reacting molecular species." Thus in the reaction by which water gas produced

the tendency of the reaction to proceed to the right equals some constant times the partial pressure of the water vapor—that is, equals $K \times P_{\text{H}_2\text{O}}$. On the other hand, the tendency to reverse and proceed to the left equals $K_1 \times P_{\text{H}_2} \times P_{\text{CO}}$. At equilibrium these tendencies are equal; hence

$$K_p = \frac{P_{\text{H}_2} \times P_{\text{CO}}}{P_{\text{H}_2\text{O}}} \quad (7)$$

in which K_p is known as the equilibrium constant of the reaction and depends only on the temperature. If it is known for any temperatures, the equilibrium pressures of these gases may be calculated for those temperatures.

¹Sitzungs-Berichte d. Kgl. Preuss. Akad. d. Wissenschaft, 1906, p. 933.

Quite generally a reaction may involve pure solids or liquids (not solutions) as participants as well as gases and may be schematically represented as follows:

$$lL + mM + \dots + qQ + rR + \dots$$

$$= uU + vV + \dots + xX + yY + \dots \quad (8)$$

where the lower case letters are integers representing the number of molecules taking place in the reaction, and

$L, M, \dots, U, V, \dots$ are solid or liquid compounds
 $Q, R, \dots, X, Y, \dots$ are gaseous molecules.

For this reaction at any given temperature the following relation similar to 7 will apply:

$$K_p = \frac{p_X^x p_Y^y \dots}{p_Q^q p_R^r \dots} \quad (9)$$

If the value of K_p for any temperature is known, the equilibrium gas pressures for the reaction can be calculated for this temperature. These pressures are conveniently expressed in atmospheres or fractions thereof, and assuming that the gases obey the simple gas laws and the partial pressure in a mixture existing at atmospheric pressure is one atmosphere times the percentage composition. Thus the pressure for CO_2 in combustion gases under atmospheric pressure containing 12 per cent of CO_2 is 0.12 atmosphere.

On the basis of the Nernst theorem and one or two other minor assumptions—namely, that the gases obey the simple gas laws and that the molecular heat of compounds at absolute zero is exactly additive—the relations shown in equations 10 and 11 may be derived. In these the equilibrium constant, K_p , is expressed in terms of the absolute temperature, the heat of reaction, coefficients depending on the rate of change of the specific heat of the compounds with temperature, and the so-called chemical constants (C). The values of these constants (C) have been computed by Nernst and are dependent on the vaporization characteristics of the gases taking part in the reaction; they are given in Table I. Other data required for the computation of K_p from these equations are found in handbooks. It will not be attempted here to derive these equations; those interested in this derivation may consult such references as Sackur-Gibson, "A Textbook of Thermo-Chemistry and Thermodynamics," McMillan & Co., 1917, or Lewis, "A System of Physical Chemistry," Longmans, Green & Co., 1918.

$$\log K_p = \frac{Q_0}{4.57T} - \Sigma g 1.75 \log T - \left(\frac{\Sigma b + \Sigma \beta}{4.57} \right) T - \left(\frac{\Sigma c + \Sigma \gamma}{9.14} \right) T^2 \dots - \Sigma C \quad (10)$$

$$\text{where } \Sigma S + \Sigma G = 3.5 \Sigma g + 2T(\Sigma b + \Sigma \beta) + 3T^2(\Sigma c + \Sigma \gamma) \quad (10a)$$

$$\text{and } Q_0 = Q_p - \Sigma g 3.5T - T^2(\Sigma b + \Sigma \beta) - T^3 \frac{(\Sigma c + \Sigma \gamma)}{2} \quad (10b)$$

where

Q_0 = the molar heat of the reaction at absolute zero;

Q_p = the molar heat of reaction at constant pressure at the absolute temperature, T , considered positive if heat is evolved in the reaction. This is the value which is computed from values of heats of formation found in handbooks;

S = molar heat of each solid or liquid substance;

G = molar heat (at constant pressure) of each gas;

$b, c, \dots$ = coefficient relating to solid or liquid substances;

$\beta, \gamma, \dots$ = coefficients relating to gaseous substances;

and ΣS = the summation of true molar heats of all solid and liquid participants; reacting mols are considered positive, resulting ones negative. The molar heat equals the specific heat multiplied by the molecular weight;

ΣG = summation in the same sense of the true molar heats at constant pressure of all gases taking part in the reaction;

Σg = summation in the same sense of all gaseous molecules;

ΣC = summation in the same sense of the chemical constants of all gases taking part in the reaction; values are given in Table I.

TABLE I. VALUES OF THE CHEMICAL CONSTANT, C , COMPUTED BY NERNST*

Hydrogen (H_2)	1.6	Nitrous oxide (N_2O)	3.3
Methane (CH_4)	2.5	Hydrogen sulphide (H_2S)	3.0
Nitrogen (N_2)	2.6	Sulphur dioxide (SO_2)	3.3
Oxygen (O_2)	2.8	Carbon dioxide (CO_2)	3.2
Carbon monoxide (CO)	3.5	Carbon bisulphide (CS_2)	3.1
Chlorine (Cl_2)	3.1	Ammonia (NH_3)	3.3
Iodine (I_2)	3.9	Water vapor (H_2O)	3.6
Hydrochloric acid (HCl)	5.0	Carbon tetrachloride (CCl_4)	3.1
Hydriodic acid (HI)	3.4	Chloroform (CHCl_3)	3.2
Nitric oxide (NO)	3.5	Benzene (C_6H_6)	4.0

*Zcit. *Electrochemie*, vol. 15, p. 687; 1909.

Our information concerning specific heats is generally not sufficient for us to evaluate the coefficients c and γ ; if we neglect this term in the equations 10 they take the following form:

$$\log K_p = \frac{Q_0}{4.57T} - \Sigma g 1.75 \log T - \frac{\Sigma b + \Sigma \beta}{4.57} T - \Sigma C \quad (11)$$

with corresponding omission of the last terms in 10a and 10b. Equations 10a and 10b also become

$$\Sigma b + \Sigma \beta = \frac{\Sigma S + \Sigma G - 3.5 \Sigma g}{2T} \quad (11a)$$

$$\text{and } Q_0 = Q_p - 3.5T \Sigma g - T^2(\Sigma b + \Sigma \beta) \quad (11b)$$

For still more approximate calculations, which are nevertheless of value in many cases, we may neglect also the coefficients b and β , and either assume that the heat of reaction at absolute zero, Q_0 , is equal to the value (Q_p) obtained from heats of formation, or consider that

$$Q_0 = Q_p - \Sigma g 3.5T \quad (12)$$

In the latter case equation 11 takes the form:

$$\log K_p = \frac{Q_0}{4.57T} - \Sigma g 1.75 \log T - \Sigma vC \quad (12a)$$

These equations, which may seem at first sight rather formidable, are in reality not difficult to evaluate with a little practice. A few illustrations may be given of their practical application.

EQUILIBRIUM IN BLAST-FURNACE GAS

What is the equilibrium composition of blast-furnace gases, CO and CO_2 , assuming that there is a slight excess of coke in the furnace?

$$\text{for which } K_p = \frac{p_{CO}^2}{p_{CO_2}} = \frac{p_{CO}^2}{1 - p_{CO}} \quad (13a)$$

(if $p_{CO} + p_{CO_2} = 100$ per cent; i.e., neglecting nitrogen).

We might judge from the negative heat of reaction that no CO could be formed in it, which is of course not true; this is a good illustration of the false conclusions to which one may be led by the application of this criterion.

Specific heat of carbon at about 25° C. = 0.16

Molar heat of carbon at about 25° C. = $0.16 \times 12 = 1.92$

Specific heat of CO₂, constant pressure, about 25° C. = 0.201

Molar heat of CO₂, constant pressure, about 25° C. = $0.201 \times 44 = 8.85$

Specific heat of CO, constant pressure, about 25° C. = 0.243

Molar heat of CO, constant pressure, about 25° C. = $0.243 \times 28 = 6.82$

ΣC (from Table I) = $3.2 - 2 \times 3.5 = -3.8$

From 10a and 10b omitting term in T^2

$$\begin{aligned} \Sigma b + \Sigma \beta &= \frac{\Sigma S + \Sigma G - 3.5 \Sigma g}{2T} \\ &= \frac{(1.92) + (8.85 - 2 \times 6.82) - 3.5(+1 - 2)}{2 \times 300} = +0.001 \\ Q_o &= Q_p - \Sigma 3.5T - T^2 (\Sigma b + \Sigma \beta) \\ &= -38880 - (-1) 3.5 \times 300 - 300 \times 300 \times 0.001 \\ &= -37920 \\ \text{And } \log K_p &= -\frac{37920}{4.57T} + 1.75 \log T - \frac{0.001}{4.57} T + 3.8 \quad (13) \end{aligned}$$

Table II shows the values computed from this equation for three temperatures in comparison with the values of the per cent CO and CO₂ actually observed by direct experiment.²

²G. Schraube, Diss. Berl. Tech. Hochschule, 1911.

TABLE II. COMPARISON OF EQUILIBRIUM PERCENTAGE COMPOSITION OF CO:CO₂C AS CALCULATED FROM EQUATION 12 AND OBSERVED

Temperature		Log K_p		Per Cent of CO in Equilibrium CO + CO ₂ = 100 per cent	
Deg. C.	Deg. Abs.		K_p	Calculated	Observed
700	973	+0.27	1.85	72	63.4
800	1,073	1.14	13.73	93	88.6
900	1,173	1.88	75.8	99	97.0

The agreement is good between observed and calculated values and would be better if better data on specific heats and heats of formation were available.

CHLORIDIZING ROAST

A knowledge of the temperature range of stability of chlorides and of sulphates is essential to the proper conduct of chloridizing or sulphatizing roasting. For instance, At what temperatures and under what conditions does Cu₂Cl₂ decompose?

Using the above equation in the short form (12a) and assuming $Q_o = Q_p$

$$\log K_p = -\frac{15,400}{T} + 1.75 \log T + 3.0 \quad (14a)$$

If decomposition occurs according to
 $2Cu_2Cl_2 + O_2 = 2Cu_2O + 2Cl_2 - 54,000 \text{ calories} \quad (15)$
 $\log K_p = 2 \log PH_{Cl_2} \log PO_2$

$$= -\frac{11,800}{T} + 1.75 \log T + 3.2 \quad (15a)$$

Or if water vapor is the oxidizer:

$$= -\frac{9,100}{T} + 1.75 \log T + 2.4 \quad (16a)$$

There is evidently little direct decomposition of Cu₂Cl₂ below about 2,000 deg. F. at which the equilibrium pressure of Cl₂ for the reaction 14a is about 1,000 parts per million. However, in the presence of air or of water vapor the decomposition according to the equations 15a and 16a will proceed at lower temperatures. If we assume 10 per cent of O₂ in the combustion gases (for purposes of calculation), it is found from these equations that at 1,600 deg. F. the equilibrium pressure of Cl₂ from reaction 15 will be 4,200 parts per million, or 0.42 per cent. When 10 per cent of water vapor is present, that of HCl will be 2.5 per cent. At these pressures the cuprous chloride would rapidly decompose in a stream of combustion gases. It is evident from the equations that the higher the temperature the less stable is the chloride, particularly in the presence of water or oxygen. It is of course well known that this chloride does decompose within this approximate range of temperatures.

STABILITY OF SULPHATES

What is the comparative temperature stability of calcium and of ferric sulphate? They both decompose into oxide and sulphur trioxide, which in turn is decomposed into SO₂ + O₂. We may take both decompositions and equilibria into account in the calculations.

$$\log K_p = \log P_{SO_3} = -\frac{20,500}{T} + 1.75 \log T + 3.5 \quad (17a)$$

$$\log K_p = 3 \log P_{SO_3} = -\frac{28,300}{T} + 5.25 \log T + 10.5 \quad (18a)$$

$$\log K_p = 2 \log P_{SO_2} + \log PO_2 - 2 \log P_{SO_3} = -\frac{9,910}{T} + 1.75 \log T + 2.4 \quad (19a)$$

We wish to calculate the temperature at which these two sulphates are in equilibrium with a combustion gas carrying 1 per cent each of SO₂ and O₂. Equation 19a becomes:

$$-2 \log P_{SO_3} = +4 + 2 - \frac{9910}{T} + 1.75 \log T + 2.4 \quad (20)$$

Equating the value of $\log P_{SO_3}$ of equation 20 first to that obtained from equation 17a and then to that from equation 18a and solving in each case for T , it is found that calcium sulphate is in stable equilibrium with 1 per cent each of SO₂ and O₂ at 1,307 deg. C. Ferric sulphate is stable under the same conditions at 649 deg. C. There is thus a marked difference in the stability of these two sulphates, which is of course well known.

OXIDATION AND REDUCTION

It is well known that there is a marked difference in the ease with which different metallic oxides are reduced to the corresponding metal. If we accomplish this reduction with a mixture of carbon monoxide and dioxide, which is generally the case, the ratio per cent CO to per cent CO₂ necessary to effect reduction may

be taken as a numerical index of the ease or difficulty of this reduction. If this ratio is high, the reduction is difficult; if low, easy.

Let us compare the ease of reduction of ferrous and of cuprous oxide by such a mixture.

Assume molar heats taken from handbook data as follows: Cu_2O , 15.87; FeO , 10.5; Cu , 5.91; Fe , 5.9; CO , 6.74; CO_2 , 8.38. We then find the following equilibrium equations:

$$\log K_p = \log P_{\text{CO}_2} - \log P_{\text{CO}} = 630/T - 0.0011T - 0.3 \quad (21a)$$

$$\log K_p = \log P_{\text{CO}_2} - \log P_{\text{CO}} = 5220/T - 0.00088T - 0.3 \quad (22a)$$

(Note that Σg becomes zero when there are as many gas molecules on one side of the equation as on the other.)

We see that a mixture of 96 per cent CO and 4 per cent CO_2 is necessary to reduce FeO at 1,400 deg. abs. (2,060 deg. F.), whereas at the same temperature a mixture of 0.6 per cent of CO and 99.4 per cent CO_2 will reduce Cu_2O .

These illustrations have shown the possibility of predicting the equilibrium conditions in any reaction entirely from thermal data (heats of formation and specific heats) together with the values of the chemical constants.

If we are fortunate enough to have determined the actual equilibrium at any temperature by independent experiment, we may use the same equations to determine it at any other temperature and of course with a considerable increase of accuracy over the previous method, for which no direct data are used. Use preferably formula 11 for this purpose. The determined value of K_p for temperature T_1 is K_1 . Substitute values of T_1 and T_2 , K_1 and K_2 in formula 11 and subtract one from the other.

$$\begin{aligned} \log K_2 - \log K_1 &= \frac{Q_o}{4.57 \left(\frac{1}{T_2} - \frac{1}{T_1} \right)} \\ &- \Sigma g 1.75 (\log T_2 - \log T_1) \\ &- \left(\frac{\Sigma b + \Sigma \beta}{4.57} \right) (T_2 - T_1) \end{aligned} \quad (23)$$

The method of application of this equation is obvious and is a most useful one whenever any direct information is available concerning equilibrium of any reaction.

From Table II it is noted that at 700 deg. C. there was equilibrium in reaction 13 when there was 63.4 per cent CO + 36.6 per cent CO_2 . Substituting these values, we may determine equilibrium at 900 deg. C. thus:

$$K_p \text{ for 700 deg. C.} = \frac{63.4^2}{36.6} = 3.0;$$

$$\log K_p = 0.477;$$

$$\begin{aligned} 0.477 - \log K_1 &= -8,310 \left(\frac{1}{973} - \frac{1}{1173} \right) \\ &+ 1.75 (2.988 - 3.069) \\ &- 0.00022 (-200) \end{aligned}$$

$$\log K_1 = 2.037;$$

$$K_1 = 109.$$

Whence

$$p_{\text{CO}} = 99 \text{ per cent};$$

$$p_{\text{CO}_2} = 1 \text{ per cent.}$$

Thus at 900 deg. C. we calculate that there must be 99 per cent of CO and 1 per cent of CO_2 for equilibrium;

these values agree closely with the observed ones given in Table II.

USEFULNESS OF MATHEMATICAL METHODS

The more values of the equilibrium constant, K_p , we have as the result of direct determination the more accurately we can write equation 10 and consequently know the value of K_p for other temperatures. If, for example, two values of the constant are determined directly, they may be used to determine the coefficients in equation 11.

It may be pointed out here that the equilibria of many reactions of great interest to metallurgists such as

have been studied experimentally; the results of these investigations are for the most part scattered throughout current periodical literature for the last fifteen years. It would be well if they could be assembled for ready reference in the reference and hand books with which metallurgists are familiar, as they are of great practical value. Many of these results may be found in the book by Lewis mentioned above as well as in Jellinek, "Physikalische Chemie der Gasreaktionen," and Haber, "Thermodynamik der Technischen Gasreaktionen."

In conclusion, it must be pointed out that the calculation of equilibrium as described above is subject to restrictive limitations. It has already been stated that the equations 10, 11 and 12 are not applicable without alteration to chemical reactions involving solid or liquid solutions, except in a very approximate manner. Furthermore, the results of such calculations from purely thermal data are necessarily not more accurate than the data on which they are based and our present knowledge of the specific heats of chemical compounds leaves much to be desired; in particular our knowledge of these specific heats at higher and lower temperatures is very meager. The author must confess that it was not the least important purpose he had in mind in writing this article to emphasize the need of the metallurgical and chemical industries for new and more accurate data on specific heats of chemical compounds, covering the widest possible temperature ranges and to make an appeal to those institutions having the equipment of these determinations to undertake some systematic work along these lines. The results of such work would have a wide usefulness and would constitute a most valuable service to our metallurgical and chemical industries.

Foreign Portland Cement Specifications

The Bureau of Standards has recently completed a summary of the portland cement specifications of various countries. This includes not only the principal requirements but also many of the details of methods of tests, details which are frequently of great importance when considering the specifications of some of the countries. However, for ready reference, the principal physical and chemical requirements have been assembled in a single chart, 16 x 22 in., copies of which may be obtained by addressing the bureau.

The Constitution of Martensite and Troostite

Hardness of Martensite Mainly Due to Fine-Grained Alpha Iron—Martensite Also Contains Carbide in Same Condition as It Existed in Austenite—Such Carbide Contracts Into True Cementite Particles to Form Troostite

BY D. J. MCADAM, JR.

Metallurgist, U. S. Naval Engineering Experiment Station

IN THE paper on "The Slip Interference Theory of the Hardening of Metals," by Jeffries and Archer,¹ these authors have made a valuable contribution to the science of metallography. Their theory of slip interference as a general cause of the strengthening and hardening of metals has made it possible to classify and explain many facts hitherto not understood.

The effect of small, hard, disconnected particles in increasing the strength of metals has thus been explained. For example, the mechanism of the hardening of duralumin by means of the submicroscopic particles of CuAl_2 is now clear.

ARE TRANSFORMATIONS IN CARBON STEELS DIFFERENT THAN IN ALLOY STEELS?

The authors' explanation of the constitution of martensite, however, would seem to require some application and possibly modification in order that all the phenomena of the hardening of steel may be properly classified. The section headings, for example, "Martensite Is Alpha Iron" and "No Cementite in Martensite," on pages 1065 and 1066 of the authors' article, at once raise the question, Do these assertions apply to

heated or cold-worked, the first transformation products have a typical, "martensitic," structure² which is usually called "martensite." In such steels, when the carbon percentage is sufficiently high, the deposition of carbides on tempering precedes and accompanies the transformation of iron from the gamma to the alpha condition. The first transformation products, therefore, contain cementite. In austenitic manganese steel, for example, according to the authors' own description of the transformation process, the first change on reheating consists in the deposition of carbides. The order of transformation in such steels is thus entirely different from that described by the authors under the heading "No Cementite in Martensite."

Evidently, therefore, the "martensites" produced by tempering austenitic steels may contain cementite. Are all the martensites produced during the cooling of steels different in constitution from the martensites produced by tempering? This subject deserves careful consideration in relation to the probable space lattice arrangements and various physical properties of quenched steels.

INFLUENCE OF GRAIN REFINEMENT IN ALPHA IRON

In discussing the subject of the constitution of martensite, consideration will first be given to Jeffries and Archer's theory that the hardness of quenched steel is due chiefly to the presence of exceedingly fine-grained alpha iron. In this discussion, for the sake of brevity, all non-gamma iron will be called alpha iron. Careful study of the authors' theory has led the writer to the conclusion that it is valid, at least as applied to hypoeutectoid steels. To account for the hardness of these quenched steels, it is not necessary to assume the presence of cementite in martensite.

I was at the first inclined to doubt the authors' conclusion that in quenched carbon steel the ferrite can be of submicroscopic grain size while the carbon is in solid solution. In quenched "Armco" ingot iron, the ferrite grains are always visible under the microscope and are often of rather large size. How is it possible, then, that quenched steel of higher carbon percentage may be composed of submicroscopic ferrite grains with carbon in solid solution? How could carbon in solid solution obstruct grain growth of ferrite?

An investigation at the U. S. Naval Engineering Experiment Station on the influence of temperature on the grain growth of iron and published in the *Proceedings of the American Society for Testing Materials*³ throws considerable light on this subject.

FIG. 1. GRAIN SIZE VERSUS ANNEALING TEMPERATURE OF INGOT, COLD-WORKED VARIOUS AMOUNTS

all microstructures that are now generally known as martensite? The authors seem to assert that "martensites" of all chemical compositions, whether produced during cooling or tempering of steel, consist of alpha iron with carbon in solid solution. Such a statement, it seems to the writer, does not correctly describe the constitution of every so-called martensite.

When austenitic alloy steels, for example, are re-

¹CHEM. & MET. ENG., June 15, 1921, vol. 24, p. 1057.

²Howe, "Metallography of Steel and Cast Iron," p. 642.
³"Annealing Temperatures and Grain Growth," by D. J. McAdam, Jr., *Proc. A.S.T.M.*, vol. 17, Part II, 1917. "Grain Size of Iron as Affected by Temperature," by D. J. McAdam, Jr., *Proc. A.S.T.M.*, vol. 18, Part II, 1918.

Fig. 1, taken from the second of the articles describing this work, shows the effect of temperature on grain coalescence⁴ of cold-worked ingot iron. As illustrated by the graphs in Fig. 1, these experiments showed that below about 1,450 deg. F. (790 deg. C.) the grain coalescence tendency is slight and is only slightly affected by temperature. From this temperature to the A_c point, however, the grain coalescence tendency increases very rapidly with rise of temperature.

Though the experiments summarized in Fig. 1 were made primarily to show the influence of temperature on grain coalescence tendency of recrystallized ferrite after various percentages of reduction by cold-working, the results throw considerable light on the influence of temperature on the grain coalescence tendency of the alpha iron formed from austenite in the quenching of hypo-eutectoid steel. Assuming that, when hypo-eutectoid steel is quenched, there is time for the formation of alpha iron but not for the formation of cementite, the infinitesimal grains thus formed would consist of but one phase. The grain growth of this phase, being unobstructed by the presence of a second phase, would depend on the time available for growth and on the grain coalescence tendency of the phase at its temperature of formation. For any quenched hypo-eutectoid steel, therefore, the grain coalescence tendency, and hence the grain size of the phase formed from the austenite, should depend chiefly on the temperature at which the austenite is decomposed. The grain coalescence tendency, and hence the grain size, of this phase would probably not differ greatly from that of pure alpha iron, if it could be formed from pure gamma iron at the same temperature. The graphs in Fig. 1, therefore, can be used in order to draw some conclusions in regard to the probable effect of carbon content on the grain size of quenched steel. In order to study this subject, the graphs in Fig. 1 must be considered in relation to the effect of carbon on the transformation temperature of austenite and in relation to the effect of carbon on the hardness of steel.

RELATION BETWEEN BRINELL HARDNESS AND A_r TRANSFORMATION

Further consideration of this subject has shown a surprising correspondence between graphs of hardness and the inverted graph of transition temperatures, both drawn with carbon percentages as abscissas. These graphs are shown in Fig. 2. Graphs A and B are plotted from hardness values for quenched carbon steels listed in Table 34 of Dr. Howe's book, "The Metallography of Steel and Cast Iron." Graph C is an inverted representation of the effect of carbon content on the decomposition temperatures of austenite as obtained by cooling curves. The data are taken from page 168 of Sauveur's book, "The Metallography and Heat-Treatment of Iron and Steel." In this graph, line Km represents the A_{cm} transitions and Kl represents the A_r temperatures. Curve D shows the maximum Brinell hardness, for any carbon content, obtained by quenching

steels at various temperatures. This curve was plotted from data taken from an article by McCance.⁵

By reference to Fig. 2, it will be noticed that, up to a carbon percentage of about 0.4, increase of hardness is most rapid and bears a nearly linear relation to the carbon percentage. Above about 0.4 per cent, however, the effect of further additions of carbon has a gradually diminishing effect on the hardness, until at about 0.7 per cent the hardness has apparently reached a maximum. Further increase of carbon percentage (at least up to 1.2) neither raises nor lowers the hardness. The similarity of the hardness graphs to graph C of Fig. 2 indicates that the hardening effect of carbon in steel

FIG. 2. COMPARISON OF HARDNESS AND TRANSITION TEMPERATURES OF PLAIN CARBON STEELS

is nearly proportional to the lowering of the transformation temperature of the austenite.

The rapid increase of hardness in proportion to the lowering of the A_r transition temperature as the carbon percentage is increased from zero to about 0.4 cannot be accounted for unless it can be shown that within this range of temperature the change of grain coalescence tendency with change of temperature is very great. Within this temperature range, however, as shown in Fig. 1, the change of coalescence tendency of iron with change of temperature is unusually great. If average diameter of grain-section after 7 hours annealing is taken as a measure of coalescence tendency, the ratio of the tendencies at 1,650 and 1,450 deg. F. (900 and 790 deg. C.) is about 10 to 1. This ratio, however, would be greater the shorter the time available for grain growth, and would probably be very great after the short period of growth available during the quenching of steel. It is, therefore, possible that the ratio between the average diameter of grain-section of pure iron and that of quenched 0.4 per cent carbon steel may be as great as 600 to 1, the ratio necessary to account for the ratio of Brinell hardness values according to Mathewson's formula.

Since the transition temperature is lower during rapid than during slow cooling, the transition temperature of 0.4 per cent carbon steel during quenching would be somewhat lower than 1,450 deg. F. (790 deg. C.). Though this secondary lowering would contribute somewhat to the grain refinement of such steel, it is believed that its influence would be small in comparison with the influence of the lowering of the temperature from 1,650 to 1,450 deg. F.

The fact that increase of carbon percentage above about 0.4 has a gradually diminishing effect on hardness

⁴If cold-worked iron is gently heated there results no change in crystallization up to a certain temperature, depending upon the amount of strain previously endured by the iron—that is, the metal is "inert." Higher anneals cause complete recrystallization, if the time is sufficiently long and the temperature sufficiently high. Metal at the point of recrystallization is known as "germinant." The grain size of ingot iron after recrystallization undergoes little if any increase until a higher temperature, about 1,450 deg. F., is reached. Above this temperature there is a rapid increase in grain size with rise of temperature until the A_c point is reached. This range of temperature I call the "coalescence range." The grain size reached at any temperature after a standard time of anneal may be taken as a measure of the "grain coalescence tendency."

⁵Andrew McCance, "A Contribution to the Theory of Hardening," *J. Iron & Steel Inst.*, 1914, No. 1, p. 192.

is evidently due to two factors. First, above a carbon percentage of about 0.35, the curve of austenite transformation temperatures does not fall so rapidly with increase of carbon percentage. Second, lowering of the austenite transformation temperature below about 1,450 deg. F. (790 deg. C.) has little effect on the grain coalescence tendency of the alpha iron formed from the austenite.

With a carbon percentage of about 0.7 the maximum hardness is reached. This would seem to indicate that

FIG. 3. FACE-CENTERED CUBIC ARRANGEMENT OF GAMMA IRON

with that carbon content grain refinement of the ferrite has reached its limit. A grain of this material, therefore, is probably the smallest possible crystal unit. Attempt at further refinement merely results in retention in the quenched steel of more or less austenite.

It seems probable, therefore, that the hardening effect of carbon, in hypo-eutectoid steel at least, is due to strengthening of the ferrite by grain refinement. The presence or absence of cementite in the martensite would probably have comparatively little effect on its hardness. Agreement with the authors' theory of hardening by grain refinement of the ferrite, therefore, does not necessarily involve agreement with their theory that

FIG. 4. FACE-CENTERED CUBIC ARRANGEMENT WHERE ONE-THIRD THE IRON ATOMS ARE REPLACED BY CARBON

"martensites" do not contain cementite. The probable condition of the carbon in martensite can be determined only by a study of the space lattice relations of austenite, alpha iron and cementite, and a study of volume, electric and magnetic relationships.

SPACE LATTICE RELATIONS OF AUSTENITE

The space lattice arrangement of gamma iron is illustrated by Fig. 3, in which the black dots represent iron atoms. The simplest assumption (that of the authors) for the space lattice arrangement of the solid solution

of carbon in gamma iron would picture every carbon atom as taking the place of an iron atom in the gamma iron space lattice. In the austenite space lattice every carbon atom would thus exert a strong influence over twelve neighboring iron atoms. The strength of this influence is shown by the fact that by the presence of carbon the temperature of the formation of alpha iron from austenite is considerably lowered.

If enough carbon could be dissolved in the gamma iron (austenite) to produce a composition equivalent to that of cementite, the space lattice arrangement of such a composition might be represented by Fig. 4, in which the carbon atoms are represented by small circles. Each of the cubes of Fig. 4 contains a carbon atom in the center of each of two opposite faces. For each carbon atom in a group of such cubes there are three iron atoms. Such a lattice structure may, therefore, be called *potential cementite*. If the carbon atoms are more widely scattered, so that there is not more than

FIG. 5. FACE-CENTERED CUBIC ARRANGEMENT WHERE ONE OUT OF THIRTY-TWO IRON ATOMS IS REPLACED BY CARBON

one carbon atom in any unit cube, potential cementite could not be formed unless, by some rearrangement of atoms, two mono-carbon cubes are brought in contact.

In the lattice arrangement illustrated by Fig. 5 every pair of mono-carbon cubes is separated by a carbonless cube. Such a structure would have thirty-one iron atoms for every carbon atom and the carbon percentage would be 0.69. In a slightly closer condensation of the mono-carbon cubes, as illustrated in two dimensions in Fig. 6, there are twenty-six iron atoms to each carbon atom and the carbon percentage is 0.825, nearly that of a eutectoid steel. In the structures illustrated in Figs. 5 and 6, there is only one plane of iron atoms between any two mono-carbon cubes. A very slight movement of any carbon atom, therefore, will result in the formation of potential cementite.

In the slow cooling of hypo-eutectoid austenite, the separation of alpha iron results in bringing the carbon atoms of the austenite closer together until their concentration is about as represented in Fig. 6. In such

a structure it would seem impossible for any two carbonless cubes to pass through the rearrangement and increase in volume involved in the formation of alpha iron from austenite without thrusting two mono-carbon cubes together to form potential cementite, and finally actual cementite. With slow or moderate cooling, that is what happens; ferrite and cementite are formed simultaneously from eutectoid austenite. The influence of rapid rates of cooling will be discussed below in connection with a discussion of the volume changes involved.

With increase in carbon beyond the eutectoid percentage, mono-carbon cubes are brought in contact in increasing numbers to form potential cementite. It therefore requires higher and higher temperatures to prevent the separation of actual cementite crystals from austenite. In austenite of the maximum carbon content, containing only twelve iron atoms for every carbon atom, the steel is at the melting point.

When hyper-eutectoid steels are slowly cooled from above the Acm line, cementite forms, and this separation continues until the eutectoid composition is reached. Since on cooling hyper-eutectoid steels cementite is formed before alpha iron, and since on cooling hypo-eutectoid steels alpha iron is formed before cementite, it seems logical to conclude that in cooling eutectoid

on quenching such steels the formation of unit cubes of alpha iron might be prevented and the excess iron might remain in atomic dispersion throughout the cementite. It is, therefore, just as reasonable to conclude that the martensite of some hyper-eutectoid steels may consist of cementite with iron in solid solution as it is to conclude that the martensite of some hypo-eutectoid steels may consist of alpha iron with carbon in solid solution.

Whether such tentative assumptions reached from study of space lattice relations alone are confirmed or disproved by recent investigations of electrical, magnetic and volume relations will be discussed below.

VOLUME CHANGES DURING COOLING OF STEEL

Electrical, magnetic and volume relations of steels quenched from various temperatures were studied by McCance.⁵ DeNolly and Veyret⁶ made experiments on the change in length of various steels throughout a range of temperatures. Andrew, Rippon, Miller and Wragg⁷ made an extensive series of experiments on electrical, magnetic and dilatation relations of steels during slow cooling throughout a range of temperature, during tempering and after quenching. Since the data on volume relations thus obtained throw much light on the constitution of quenched steels, the writer has assembled and rearranged the essential parts of the data so as to bring out these relations most clearly. Since the dilatation experiments of DeNolly and Veyret, and of Andrew, Rippon and Miller, consisted of measurement of changes in length, the corresponding percentage changes of volume have been calculated from their results for comparison with McCance's results.

The results of these experiments show that the total volume change of any steel on slow cooling through the critical range is made up of two distinct and definite parts: an expansion due to the change from gamma to alpha iron; a contraction due to change in iron-carbide from the condition in which it occurs in austenite to cementite. The gamma-to-alpha expansion decreases and the carbide contraction increases with increase in carbon content. In steels having less than about 1 per cent, the allotropic expansion exceeds the carbide contraction, so that the net result is an expansion. In steels having more than about 1 per cent carbon, the carbide contraction exceeds the allotropic expansion, so that the net result is a contraction. The way in which these two factors vary with carbon content is shown in Fig. 7, in which graph A represents the effect of carbon percentage on the allotropic expansion, and graph B or C represents the effect of carbon percentage on the carbide contraction.

The work of the above-mentioned investigation has shown that, by rapidly cooling steels from above the critical range, it is possible to suppress entirely the carbide contraction, while permitting the gamma-to-alpha expansion to take place. This results in a "martensitic" structure. These experiments would indicate that the gamma-to-alpha expansion in the steels investigated is much more rapid than the carbide contraction. For this reason it is necessary to modify somewhat any conclusions that may be reached by study of space lattice relations alone. Even when the space lattice

FIG. 6. PLAN OF ARRANGEMENT WHERE ONE OUT OF TWENTY-SEVEN IRON ATOMS IS REPLACED BY CARBON

steel the cementite and alpha iron are formed simultaneously. This reasoning, as well as the study of space lattice relations, therefore, leads to the conclusion that the authors are incorrect in their assertion that in eutectoid steels more migration of atoms is required for the formation of cementite than for the formation of alpha iron.

In the austenite of hyper-eutectoid steels of the higher carbon percentages the iron atoms not in the immediate sphere of influence of carbon atoms are so widely scattered that migration would be required for the formation of alpha iron. It is possible, therefore, that

⁵H. DeNolly and L. Veyret, "Note on the Transformation of Steels," *J. Iron & Steel Inst.*, 1914, No. 2, p. 165.

⁷Andrew, Rippon, Miller and Wragg, "The Effect of Initial Temperature Upon the Physical Properties of Steel," *J. Iron and Steel Inst.*, 1920, No. 1, p. 527.

grouping is such that no atomic migration is necessary for the formation of cementite on cooling, the change from potential to actual cementite is relatively so slow that it can be prevented without prevention of the change from gamma to alpha iron. With the possible exception of hyper-eutectoid steels of the higher carbon content, therefore, quenched steels may contain alpha iron and at the same time be free from actual cementite.

HYPER-EUTECTOID TROOSTITE

The above-described investigations of volume changes did not include carbon steels having more than about 1.2 per cent carbon. In the discussion of the space lattice relations of austenite it was shown that in the cooling of hyper-eutectoid austenites of the higher carbon percentages, unit cubes of alpha iron could probably not be formed without migration of iron atoms. The time required for this migration might, therefore, be expected to slow down the allotropic expansion so that it would be preceded and accompanied by the carbide contraction. The fact that in such steels the carbide contraction considerably exceeds in volume the allotropic expansion would probably make it more difficult to suppress this contraction while permitting the allotropic expansion to take place.

Even if by rapid cooling the carbide change in hyper-eutectoid steels can be prevented without preventing the allotropic change, there must be some intermediate rate of cooling such that the carbide contraction and allotropic expansion will take place simultaneously. The writer, by quenching hyper-eutectoid steels of the higher carbon content in oil at 300 to 400 deg. F. (150 to 200 deg. C.) has obtained structures, apparently "martensitic," in which the carbide and allotropic changes have occurred simultaneously. By quenching hyper-eutectoid steels at suitable rates, therefore, as well as by tempering hyper-eutectoid austenitic alloy steels, "martensitic" structures are obtained. According to the authors' definition of martensite, these so-called "dark etching martensites" should be renamed "hyper-eutectoid troostite."

PROBABLE CONDITION OF CARBON IN MARTENSITE

A study of the volume relations of cementite, alpha iron and gamma iron throws some light on the condition of the carbon in martensite. Though the space lattice arrangement of cementite is not known, the approximate relation between the volumes occupied by the same number of atoms of cementite, alpha iron and gamma iron can be calculated. The specific gravity of cementite, according to Benedicks, is 7.74 in steels having less than 1.26 per cent carbon. The specific gravity of pure iron, according to the same authority, is 7.87. If cementite had the same space lattice as alpha iron, its specific gravity would be about $\left(\frac{180}{224}\right)$ times that of alpha iron) 6.22. Since the specific gravity of cementite in steel having less than 1.26 per cent carbon is 7.74, the volume occupied by the same number of atoms in cementite is only 87.3 per cent that of alpha iron. The contraction of volume if iron carbide changed from the alpha iron space lattice to that of cementite would, therefore, be about 12.7 per cent.

In Fig. 7 the ordinates of the line *D* represent the percentage changes of volume that would occur if all the iron carbide in steel changed from the alpha iron

space lattice to that of cementite. The ordinates of the line *E* represent the volume changes that would occur if all the carbide in steel changed from the gamma iron space lattice to that of cementite. Lines *A* and *E* are both drawn on the assumption that the allotropic volume change in pure iron, if it could be measured at room temperature, would be practically the same (1.2 per cent) as the actual measurements that have been made at the transition temperature. Since the volume-temperature curves of gamma and alpha iron probably separate somewhat as the temperature falls, the allotropic change of volume if measured at room temperature may be somewhat greater than 1.2 per cent. Any change in the position of line *E* on this account, would, however, be relatively slight.

In graph *B*, plotted from data on carbon steels in the article by McCance⁹ previously referred to, the ordinates represent the maximum carbide contractions measured at room temperature. In graph *C*, plotted from

FIG. 7. VOLUME CHANGES IN STEEL DUE TO ALLOTROPIC TRANSFORMATION AND CEMENTITE FORMATION

data in the article by Andrew, Rippon and Miller⁹ previously referred to, the ordinates represent the maximum carbide contractions measured within the temperature range in which they occur. Allowing for experimental errors, the agreement between these two series of measurements is very good. A curve drawn half way between curves *B* and *C* would, therefore, probably represent correctly the carbide contraction as influenced by carbon percentage.

Comparison of graphs *B* and *C* with lines *D* and *E* of Fig. 7 shows that the carbide contraction is a little more than half what it would be if the carbide change were from either the gamma or alpha space lattice volume to that of cementite. It is evident, therefore, that neither in austenite nor in martensite does the space lattice of the carbides correspond to that of either gamma or alpha iron. The iron atoms surrounding every carbon atom in austenite must be more closely packed than the iron atoms that are not in the immediate sphere of influence of a carbon atom. When the steel is so quickly cooled that the carbide change but not the allotropic change is suppressed, the volume occupied by every carbide group remains practically unchanged. This would seem to indicate that in martensite every carbon atom with its surrounding iron atoms

preserves essentially the same space lattice arrangement that existed in austenite. These carbide groups, though they are in a denser space lattice than the average space lattice of austenite, will be designated "austenitic carbide" groups.

It seems probable that in austenite every carbon atom holds its twelve neighboring iron atoms at a radial distance that is smaller than it would be if the carbon atom were replaced by an iron atom. Such a shortening of the radial distance need be relatively slight to account for the difference between the ordinates of graph *E* and those of graph *B* or graph *C* of Fig. 7. In martensite the density, and probably the arrangement, of an austenitic carbide group is practically the same as in austenite.

When opportunity is given for two austenitic carbide groups to come in contact (forming potential cementite) and to undergo the necessary great contraction of volume, actual cementite is formed. In order of increasing coarseness of the cementite particles, the resulting microstructures are known as troostite, sorbite or pearlite respectively.

Martensite, therefore, probably consists of alpha iron with austenitic carbide in suspension. It is not quite correct to say that the carbon is in solution in the alpha iron, since that would imply that every carbon atom in martensite takes the place of an iron atom in the alpha iron space lattice (in which every atom is surrounded by only eight other equidistant atoms). Such a loose arrangement of the austenitic carbide groups would not be likely to exist, since it would be opposed by the tendency of the austenitic carbide groups to undergo "carbide contraction."

SUMMARY

(a) Jeffries and Archer's conclusions in regard to the causes of the hardness of martensite seem to be confirmed by results of experiments at the U. S. Naval Engineering Experiment Station on the effect of temperature on the grain coalescence tendency of ingot iron.

(b) If the term "martensite" is to be limited so as to apply only to the constituent of steels in which the allotropic expansion but not the carbide contraction has occurred, the constituents, usually designated "martensite," of some hyper-eutectoid steels should be known as "hyper-eutectoid troostite."

(c) Martensite consists of alpha iron with "austenitic carbide" in suspension. In troostite, the austenitic carbide has undergone the "carbide contraction" to form cementite particles of the smallest size that can exist independently.

Production Costs in Belgian Plate-Glass Industry

Acting Commercial Attaché Samuel H. Cross reports that in general wages in Belgian plate-glass plants approximate four times the pay received by employees in this industry in 1914. It is estimated that the production costs now have reached 600 per cent of those prevailing before the war. This advance is due not only to the increase in raw material costs and wages but also to the introduction of the 8-hr. day. This has necessitated the use of three shifts per day instead of two, which was the pre-war practice.

It is estimated that in the total production cost labor enters for 16 per cent, coal for 21 per cent, raw materials for 47 per cent and maintenance 10 per cent. The estimated cost of sales, agencies, warehousing and travel amounts to 4 f. per sq.m.

Spectroscopic Examination of Converter Flame*

BY W. J. CAMPBELL

The spectroscope is more extensively used on the Continent than in this country for the examination of converter flames. The usual practice here is to take the blow completely down, thus eliminating practically all the carbon, and thereafter to recarbonize with suitable fluid metal additions. In many Belgian and Swedish foundries engaged in the production of small steel castings the blow is brought down before the flame has completely dropped. Without any additions of recarbonizers the molten metal may contain 0.40 to 0.60 per cent carbon. The usual additions are added molten. The resultant steel is extremely hot and fluid, and is shanked from the converter in hot crucibles. The amount of short-run castings and skulls is considerably lower than with the usual procedure of completing the blow and either casting low-carbon steel or adding high-carbon metals.

The spectroscope is useful for indicating the point at which to bring down the blow in the second method of working. Many attempts have been made to obtain higher carbon steel by this method without the use of a spectroscope, but the great uncertainty and the erratic results secured condemned the practice. With the aid of the spectroscope better and more regular results may be obtained, but the process is still not so accurate as the practice of completely blowing and recarbonizing for obtaining a pre-arranged carbon content to within, say, a few points. The spectroscope is not so essential for judging the finish of the blow as for examining the carbon flame before the whole of the carbon has been completely burnt off.

At the beginning of the blow the spectrum is continuous and indefinite. With the faint appearance of the flame the characteristic yellow line of sodium is seen. For a short period this line is very faint and appears in flashes. As the flame gradually increases and becomes steady, the sodium line becomes stationary and brighter. As the flame and temperature rise the spectrum lines become more complex. The line spectrum of thallium and lithium and the banded spectrum of many other metals may be observed, but they are not of any particular value for the control of the blow. The principal lines to be noted are the carbon lines, which appear bright green. They are faint at first, but gradually, as the flame rises, they become brighter and more distinct, until, with the falling of the carbon flame, they diminish in number and fade completely away with the final drop of the flame.

The advantage for many classes of small foundry work of obtaining very hot and fluid steel may well repay the cost of installing a spectroscope.

The following table gives a brief outline of an average blow and its spectroscopic examination.

Duration of Blow	Eye Observation	Spectroscope Observation
3 min.....	Sparks, but no flame...	Faint flashes of sodium line in continuous spectrum.
3 to 10 min. ...	Flame gradually appearing at mouth of vessel and increasing	Yellow sodium line becoming stationary and bright. Also lines of thallium and lithium and bright green carbon lines.
10 to 12 min...	Flame brighter and longer and temperature rising	All the above lines fixed and brighter, the carbon lines being especially clear.
12 to 14 min...	Flame at maximum height and brightness.	Addition of green carbon lines in blue and green. All lines at their maximum brightness.
14 min. to completion of blow.....	Flame falling gradually.	Carbon lines not so luminous and gradually fading with dropping flame and eventually disappearing with the end of the blow.

Glimpses of Ohio Ceramic Industries—II

Crooksville China Co., Located at Crooksville in Southern Ohio, Manufactures Tableware by Employment of Technical Methods—Preparing the Slip—Materials for Pottery Bodies—Scientific Study of Clay Body Composition—Alkali Treatment of Casting Slip—Constitution of Glazes*

By CHESTER H. JONES

LOCATED at Crooksville, in the same southern Ohio district, near the previously described plant, the Crooksville China Co. is engaged in the manufacture of medium grades of china- and dinner-ware, employing to a large extent the American clays as raw material, although some items are imported.

SAGGERS

Recent investigations of the American Ceramic Society have shown that the nature of the sagger, or burned clay box, holding the ware during burning is a most important consideration for any process where the pieces must be protected from mechanical action in the kiln. All saggars employed at this plant are hand-molded from raw materials, one-third of which is native Ohio clay, the remainder coming from other clay fields of America, excepting a small quantity which is imported. The stoneware clays mined in this district make excellent saggars. Hand-molding assures a more uniform consistency or temper to the finished sagger without the chance for laminations so common to machine-pressed saggars. Drying is accomplished by placing saggars on shelves located over a brick gas flue from the kilns. They are subsequently glazed and burned.

PREPARING THE SLIP

Materials used in the manufacture of the china are North Carolina china clay, Florida china clay, English ball clay, English china clay, feldspar and flint. These are delivered from the railroad cars to bins, from which they are drawn to an industrial hopper car on narrow-gage track running along the front of the row of bins. Definite quantities are weighed into the car by placing it over track scales. Each charge weighs about 1,400 lb. and fourteen charges are made each day. The car is emptied to the blungers, or vertical steel tanks equipped with agitating paddles, where, mixing with water, the creamy solution or slip is beaten to a uniform consistency. All the clay-working machinery in this factory is made by the Patterson Foundry & Machine Co.

MATERIALS FOR POTTERY BODIES

In general the preparation of white ware bodies or porcelains involves the use of clay, flint and fluxes. Either kaolin or china clay, or both, may be used, and ball clay may be employed, as in this instance. The kaolin may be either English or domestic, fineness of grain being the main distinction between the two. The English kaolin works up to a finer slip. Ball clays add to the strength and vitrification properties of the ware.

Neither the English nor German potteries use ball clay, but substitute a plastic kaolin.

The added flint is silica, and ground sand is substituted for flint in the United States. Rock quartz is sometimes used instead of flint, although it is costly to grind. Silica from southern Illinois has recently been considered a promising material for pottery bodies. True flint is a pebble gathered on the coast of France having an average egg size and a dark gray to white color. It is exported to the United States and calcined in rotary kilns. This operation burns out the organic material, causing the pebbles to soften and turn to a whiter color. These pebbles are subsequently crushed in a chaser mill and ground in ball mills using raw flint pebbles for a pulverizing medium.

There is less of this material on the market each year. It can be distinguished from ground sand only by the aid of the polarizing microscope, for there is chemically no difference between the flint and sand; possibly the sand is purer. Flint, being formed in the chalk cliffs of the English Channel, contains more lime. Sand is prepared by grinding in ball or tube mills.

FLUXES

Fluxes are often added to assist vitrification. Lime may be added as CaCO_3 in amounts up to 2 per cent to make the feldspar active. In Holland 30 per cent of lime is introduced and the ware is burned at a low heat. This gives a very porous body, which takes a high tin oxide glaze and is known on the market as Delft ware.

Other fluxes in use are magnesia, light and heavy, steatite or soapstone, and feldspar. Of all these feldspar is the most important and a good commercial grade will have the following analysis:

	Per Cent		Per Cent
Al_2O_3	16.76	K_2O	9.80
SiO_2	69.45	Na_2O	2.60

Potash feldspar contains about equal amounts of soda and potash. It is a white mineral occurring in dikes in Maine, Connecticut, New York, Pennsylvania, Virginia and the Southern States. It is quarried, hand-picked and ground in ball mills. Soda spar is about the same grade of material, but is a softer mineral. Lime spar is not used by the potter. Of the market grades, No. 1 spar is carefully selected hand-picked material, while No. 2 is the standard grade, having an Fe_2O_3 content less than 0.20 per cent.

FLUXING ACTION OF FELDSPAR

Below cone 0.05 feldspar acts as a grog, but at higher temperatures is a neutral flux behaving in a steady and uniform manner. It is frequently spoken of in burning operations as a solvent, since it performs on the other

*For Part I see CHEM. & MET. ENG., vol. 25, No. 12, p. 562, Sept. 21, 1921.

constituents like water on sugar. From 19 to 20 per cent is needed in a body mixture to get complete vitrification of the mass. It exerts a marked positive effect on the translucency of the ware. In the kiln it lowers the coefficient of expansion of the mixture to a small but important extent to prevent crazing or cracking of the glaze.

Cornish stone is similar to feldspar, but harder. It contains more silica, less alkali and less iron. It also has a fluorspar content. English potters use it mainly from tradition and habit, for it is without particular commercial value at the present time.

SCIENTIFIC STUDY OF BODY COMPOSITION

The clay-working business, particularly the pottery industry, has been a mystery to the layman mainly because he has been unable to see how the particles of a body form. Old-time potters have taken advantage of this, claiming to have special knowledge handed down on the death bed from father to son. They claim that new grinding methods do not give the same size and shape of particle as their own crude traditional processes of size reduction. As a matter of fact, the method is immaterial so long as uniformity of particle size is secured to give strength to the mass. Material which is too fine may cause dunting.

Ceramists and physical chemists have among other things found that the study of bodies by triaxial diagrams has done much to dispel the mystery surrounding body mixtures. The slow accumulation of such diagrams in scientific publications as worked out by the various investigators for all sorts of possible body materials is going far toward putting the pottery industry on a scientific basis. It is upon such industrial research that the future progress of the ceramic industries depends.

OBTAINING THE PLASTIC MATERIAL

After the proper constituents have been thoroughly blunged at the Crooksville plant the slip is drawn into the lawns, which are revolving cylindrical frames covered with bolting cloth, each lawn consisting of two concentric cylinders, so that the material is screened twice. This operation rejects all the coarse material in the slurry or slip. Double-piston pumps acting at 100-lb. pressure convey this slip from the agitated slip cistern below the lawns to the three plate-type filter presses. The water from these presses is stored and eventually returned to the blungers for the production of subsequent slip.

The smooth putty-like cake from the filter presses is thrown into a pug mill (English type, Windsor), whence it is extruded. Cake as it comes from the filter presses contains about 25 per cent water, which is not uniformly distributed. The pug mill, which consists essentially of a closed screw conveyor, extrudes an evenly tempered product.

ALKALI TREATMENT

Pugged clay is transferred to the first of a pair of casting slip mills operating in series. They are simply tanks of concrete and steel, equipped with agitating mechanisms like the blungers previously mentioned. The material enters the first and after a time is allowed to flow to the second one, located at a lower level. Each slip mill charge consists of 1,000 lb. of pugged clay, six buckets of water, 20 oz. of soda ash and 10 oz. silicate

of soda, the two latter being mixed with the water. After a thorough blunging in the slip mills the product is pumped to the upper floors.

The purpose of alkali treatment of clays for purification and use in the casting process is well outlined in Technologic Paper 51, U. S. Bureau of Standards, by A. V. Bleining. Alkalis tend to hold the clay in suspension in a fine-grained and jelly-like mass or state of deflocculation. The viscosity of the clay-water system is caused to change so that a constant degree of fluidity can be maintained by the use of the sodium salts added. Opposite effect or precipitation can be had by using acid electrolytes.

The casting process used in producing cup handles and irregular pieces such as vegetable dishes, pitchers, etc., consists of pouring this thick water suspension or slip from the mills into plaster of paris molds of the desired shape. The porous plaster begins at once to absorb the water from the slip and a coating of the clay body forms on the surface of the mold. When the desired thickness of ware is obtained, the remaining slip is poured off, leaving an article of the required shape.

With partial drying the body then stiffens and shrinks away from the mold, permitting the removal of the piece for complete drying. If the casting slip were made up with pure water, the resulting shrinkage would be very high, causing damage to the shape. The addition of the sodium carbonate and silicate reduces the amount of water required to form the solution, and consequently the drying shrinkage is lessened. Furthermore, a settling of the slip previous to the casting of the piece causes larger particles to precipitate from the solution.

The above-mentioned bulletin describes tests which show that the washing of kaolinitic clays may be decidedly improved as far as the quality of product is concerned by adding caustic soda or soda ash and sodium silicate in definite small amounts in the blunger. It makes possible more complete sedimentation of the undesirable granular impurities, improves the color of most clays where whiteness is desired, enriches the content in the clay substance, decreases drying shrinkage and tends to increase burning shrinkage. Clays containing iron as finely divided ferric oxide cannot be successfully treated by this process. Sodium hydroxide is absorbed to a far greater extent than the carbonate and probably combines chemically with the clay.

PREPARATION OF GLAZES

The large part of the product of this factory involves the use of a white glaze in which the ware is dipped and subsequently burned. Materials used include feldspar, zinc oxide, white lead, whiting, paris white (lime), and china clay. Frit, or artificial glassy ingredients, previously prepared is added to and ground with these materials. This frit is prepared by mixing boric acid, borax and flint, pouring the mixture into a sagger and burning to a glass in the kiln. On cooling it is broken up for mixing with other glaze substances.

The ingredients of the glaze are mixed wet and ground in three Patterson pebble mills, each containing 1,000 lb. of pebbles. After a thoroughly ground mixture is obtained it is drawn through lawns to remove grit and dirt and is then ready for the dipping room. Other equipment in the glaze room is a pebble mill and vertical cylinder mill for preparing sagger glazes. The

saggers are glazed to prevent pieces from chipping off and falling on the ware to its damage while in the bisque kiln.

CALCULATION OF GLAZES

Potter's or trade recipes for glazes are usually expressed in the form of batch weights and have been evolved in the past from practical experiments after the manner of cooks rather than ceramists. These formulas have "just happened" after generations of rule-of-thumb ceramics, which is no guarantee that they are the best possible mixtures. Our leading ceramic schools, on the other hand, have attacked the glaze problem in a scientific manner and in the compounding of both glazes and bodies now employ methods of calculation which might be called ceramic stoichiometry. Empirical formulas are used to express the compositions of materials and mixtures. They show in a way the actual chemical composition, since they contain the relative molecular proportions of the various oxides. They do not, however, attempt to represent the actual chemical or mineralogical constitution. This is simply another step forward in the analysis for the chemical control of the ceramic industry.

Seger was the first to adapt this stoichiometric method of mineralogists to ceramic work, and ceramic chemists almost without exception now use it. In a lecture course at Illinois University, Cullen W. Parme-

ular parts of each group present. In clays and many of the minerals used as ceramic materials the proportion of basic oxides is very small and it is found of advantage to make the coefficient of Al_2O_3 equal 1. This has been adopted as a custom and the mineral or body formula is expressed as $xRO \cdot Al_2O_3 \cdot ySiO_2$. Thus orthoclase has the formula $K_2O \cdot Al_2O_3 \cdot 6SiO_2$, and kaolinite is expressed as $Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$.

"In glasses, glazes and enamels the Al_2O_3 has a wide variation and frequently is absent. The RO oxides here play an important part, and the custom has been adopted of making RO equal 1 and giving to the Al_2O_3 and SiO_2 suitable coefficients to represent their relative molecular proportion. The general glaze formula is, then, $RO \cdot yAl_2O_3 \cdot zSiO_2$. It is to be remembered that RO represents the sum of the oxides and their individual molecular proportions are such that the sum equals 1.

"In glasses, glazes and enamels the Al_2O_3 may vary widely and is frequently absent, while the oxides of the mono- and bi-valent metals may be varied and substituted, but are always present. As a matter of convenience in comparison of formulas it has become the custom in the case of glasses, glazes, etc., to use such minor numerical coefficients to express the molecular proportion of the various oxides as to make the sums of the basic or RO members equal to unity. The general formula in this case becomes $RO \cdot yAl_2O_3 \cdot zSiO_2$. The composition of a porcelain glaze is expressed as

or a stoneware glaze as

These formulas must not be confused with the chemical formula of a compound. They merely express in a convenient way the proportions of various oxides present, although they are not introduced as such, nor do they exist in definitely known compounds in the glaze."

SHAPING THE BODIES

Plates, the bodies of cups and similar regular pieces are thrown on the jigger, while cup handles and irregular pieces as previously described are slip castings. Fig. 7 shows a group of workmen attaching handles to cup bodies, the plaster of paris slip-casting molds for handles appearing in a row on the bench in the background. The clay is slightly wetted at the points of contact between handle and cup, causing the two clay parts to weld to form one piece. This work is carried on very rapidly on piecework basis, as are most of the other operations in the plant.

The jigger or jolly is essentially a potter's wheel revolving in a horizontal plane with a plaster of paris mold conforming to the outside shape of the piece mounted thereon. The inside shape is obtained by throwing down a steel cutting tool to a set position after the machine starts to revolve. Ordinarily three operators work at each large jigger. The "batter out" throws a lump of plastic body clay of approximately the desired amount upon the adjacent table and flattens it out to approximate thickness and shape by striking with a flat paddle or iron block with a handle. The jiggerman seizes it, throws it into the jigger and pulls down the hinged cutting tool to position, trimming out the

FIG. 7. ATTACHING HANDLES TO CUP BODIES

lee explains the procedure of calculations as outlined in the following paragraphs:

"In the construction of the formula the oxides of the mono- and bi-valent metals, which form bases and act as such in silicate fusions, are grouped under a general heading, RO. These include the alkalis, alkaline earths and most of the coloring oxides, CuO , CoO , FeO , MnO , etc. The oxides of the trivalent metals are generally grouped with the Al_2O_3 , which is almost always present. Alumina plays a double rôle in that it may act as a base or as an acid, depending upon the conditions. The R_2O_3 group is often referred to as the intermediary group in glaze compositions. Silica (SiO_2) is the principal oxide of the acid group. In some cases it may be partly replaced by other acid oxides, but it is generally present in considerable amounts. Ceramic products may be generally considered as silicates, or silicate mixtures.

"The ceramic formula representing a mineral ingredient, a body, a glass or a glaze may be expressed in the general form $xRO \cdot yAl_2O_3 \cdot zSiO_2$, where x , y and z are numerical coefficients indicating the number of molec-

surplus clay. He then removes it to a table on the opposite side, where irregularities are wiped off with a wet cloth or brush by the third operator. Finally it is laid upon a movable rack or tray. All clay is transferred to the jiggers by elevators and overhead trams with traveling platforms.

DRYING

The racks containing the finished shapes are transferred by hand to the driers. The drying chambers consist of rooms divided off by wooden partitions with steam pipes passing around the sides. From five to six hours are consumed in drying the ware. This time is sufficient because of the thin walls common to china-ware objects.

BURNING

The dried pieces are conveyed to the kiln room, where they receive the bisque burn. The kiln room equipment consists of four bisque kilns, five gloss or glaze kilns and eight decorating kilns. Natural gas at 45c. per 1,000 cu.ft. is employed for fuel. Fig. 8 shows a corner

FIG. 8. VIEW OF KILN ROOM

of the kiln room with saggers stacked in the background and the entrance to one of the bisque kilns on the right. The bench in the right foreground with plates and saggers stacked on the shelves is employed in loading the ware in the saggers. To prevent sticking pieces are separated in the sagger by resting each on small triangular section clay supports imbedded in the sagger wall at an angle so that the contact where the piece rests is a sharp point of clay material. In this way the small protuberance of clay sticking to the piece after the burn may be broken off by a sharp blow in the chipping room.

GLAZING

The saggers are stacked in the kiln in such a manner that those containing large pieces are in the center and the smaller ware near the outside of the circular kiln. Firing time in the bisque kilns ranges from forty-eight to fifty hours and a temperature of cone 8 is attained. After this treatment the ware is removed to the dipping department, where the glaze is applied by simply dipping each piece in a tub of the glaze solution, the preparation of which has been described. It is then returned to the glaze kilns, where it is fired from twenty to twenty-six hours at a maximum temperature of cone 4. Cones are used in regulating the

bisque and gloss kilns, while the veritas disk is employed in the decorating kilns.

DECORATING

After chipping off the supports previously mentioned, the pieces are transported to the decorating department. Here either transfer method or hand-painting is employed in putting on decorative designs. In the transfer process the portion to be decorated is first treated

FIG. 9. INTERIOR OF A DECORATING KILN

with a coat of ordinary shellac brushed on as a binder for holding transfer paper in place. The designs are printed on the decalcomania paper with special inks. This paper is purchased from the manufacturer in strips and sheets of varying shapes to fit the piece and is covered with numberless different designs. Rubber stamps with special inks and stamp pads are also used in some cases. Hand painting is employed chiefly in decorating cup handles and edges. Fig. 9 shows the interior of a

decorating kiln with the dishes stacked on knock-down shelves. Eight hours is required to burn on the decorations and a temperature of about cone 0.015 is reached. This is sufficient thoroughly to penetrate the glaze with the colors. The shellac binder and paper are entirely volatilized and the finished pieces are finally removed from this last process. The wholesale price of china-ware is largely determined by the method and type of decoration.

The summation of impressions after a walk through this plant leaves with the observer the thought that the manufacture of tableware is a nice business. The factory is spotlessly clean, light and well ventilated, giving ideal conditions for the employees and reflecting good cheer in the personnel of the operating staff.

Zinc in the First Half of 1921

The Geological Survey reports that the smelter production of zinc from foreign and domestic ores for the first six months of 1921 totaled 102,525 tons, as compared with 258,108 tons in the same months of 1920 and 205,269 tons in the last half of 1920. The stock of zinc held at smelters and in warehouses June 30, 1921, was 94,747 tons, compared with 71,037 tons at the end of 1920 and 29,892 tons one year ago. The apparent domestic consumption of zinc, taking into account imports and exports, amounted to 83,965 tons in the first half of 1921.

The number of retorts in operation on June 30, 1921, was 36,000, compared with 56,000 at the end of 1920 and 75,000 on June 30, 1920.

Synopsis of Recent Chemical & Metallurgical Literature

Elastic Limit—Prof. William Dalby, in a paper read before the Engineering Conferences of the Institution of Civil Engineers, June, 1921, notes that the limit of proportionality between stress and strain during tension loading has often been called the elastic limit, but such a term conveys the idea that the elastic power of the material is exhausted, which is by no means true. Metal possesses elastic properties right up to the instant of fracture.

The author has devised an optical automatic recorder of great sensitivity and precision, and finds that if a bar strained beyond the limit of proportionality be unloaded, the piece will spring back and to all appearances acts like a perfect spring. Investigation shows, however, that no part of the stress-strain curve on unloading or reloading is a straight line. In fact such procedure always draws loops

like Fig. 1, the areas increase on subsequent reloadings at first rapidly in some materials, tending to a limiting value.¹

From a practical point of view, therefore, the term elastic limit should mean the limit where proportional elasticity ends and unproportional elasticity begins. Proportional elasticity is destroyed by overstrain; in alloy steels it remains so, as shown in the successive curves in Fig. 2. Iron and soft steels tend to recover their property of proportional elasticity by mere lapse of time—very short on moderate tempering, merely boiling in water. Alloy steels and high-carbon steels recover only after a high anneal (550 deg. C. for 1 hour for the last curve of Fig. 2).

Dr. Rosenhain observed that both the "limit of proportionality" and the "limit of restitution" depended upon the accuracy of measurement. It is impossible to determine the former by noting whether or not a loop was formed on successive loads, since there is always a certain thermal effect due to elastic stretching; in some cases a rise of temperature, in some a slight fall. If one allowed time for that temperature difference to vanish, the energy was changed, and when the load was taken off, a loop in the stress-strain diagram was bound to occur.

The heat generated in slow stretching of a piece of metal is always less than the mechanical work done, on account of the internal changes produced. The difference varied widely with different metals. In iron particularly, the amount of heat generated is very nearly the whole of the work done; therefore a very small loop (indicating internal work) would result. In copper the loop would be large; in aluminum larger still; the size varies inversely with the melting point and the latent heat of fusion.

Absorption of Nitrogen Oxide by Sulphuric Acid.—The analysis of higher nitrogen oxides requires that they shall first be absorbed by sulphuric acid. The transformations which they undergo during this absorption has led to many interpretations. Thus some authors, especially those who use physical methods, admit the direct passage from NO into NO₂, whereas those using chemical methods have noted in some cases the presence of N₂O₃. This contradiction has been solved by Wourtsel (*Comptes rendus*, vol. 170, 1920, p. 109) who has shown that there is no total decomposition of

N₂O₃ into NO + NO₂, and that NO can combine only partly with NO₂ to give N₂O₃, so that amounts of N₂O₃ up to 6 per cent can exist under atmospheric pressure. This small quantity, due to its great aptitude to react and to be regenerated rapidly at the expense of NO and NO₂, causes the formation of nitrous derivatives in the presence of absorbing reagents. This explanation is more satisfactory than that of Lunge, who stated that NO₂ and NO in the presence of H₂SO₄ would result in the reactions

A. Sanfourche has made a series of tests to determine whether the reactions as indicated by Lunge take place (*Comptes rendus*, vol. 172, June 20, 1921, p. 1573.) He has found that when nitrous gases whose total composition approaches N₂O₃ react with sulphuric acid they do not behave as would a simple mixture of NO and NO₂. He concluded that the reactions taking place are

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

New Type of Cascade Pan.—Ludwig A. Thiele, of Columbus, Ohio, has patented a new cascade pan of the type which is usually employed in the concentration of sulphuric acid. The pan has an open top, vertical side walls and a deeply corrugated bottom. As will be noted in the accompanying diagrams, there are a number of baffle plates in each pan which are so fixed that the acid flowing through the pan is compelled to follow a tortuous path, and since it is exposed to the extended heating surfaces of the pan, rapid evaporation is thus effected. The pans

are so adapted that they can be assembled end to end in the cascade commonly used in concentration plants. The construction of the pan can be noted from the figure. The side wall 3 to the pan 1 are suspended in an intermediate position in the pockets 5 by the vertical ribs 7, which form sockets 8 for the baffle plates 9. (1,380,689; June 7, 1921.)

Separation of Borax From Potassium Salts.—Crude salts such as those obtained from Searles Lake, California, by concentration and cooling of the brine, are heated and the water they contain is sufficient to cause the borax to be redissolved. If the hot mixture then is spun in a centrifuge, the liquor containing the borax is effectually separated from the potassium salts, which can be further purified by spraying with a small amount of hot water. It is claimed that a very pure product can be obtained in this manner. (1,382,825; Clinton E. Dolbear, assignor to Industrial Research Co., of San Francisco, Cal., June 28, 1921.)

Manufacture and Uses of Selenium Oxychloride.—Victor Lenher has been granted a number of patents relating to various methods of preparing selenium oxychloride and a number of important uses for this article. In patent 1,382,920 the preparation is carried out by combining selenium

¹"Researches on the Elastic Properties and the Plastic Extension of Metals," *Phil. Trans.*, Series A, vol. 221 (1920).

tetrachloride, which is a white crystalline solid, directly with selenium dioxide, also a white crystalline solid, to form the liquid selenium oxychloride. The product as it is formed acts as a solvent for the constituent materials and thereby facilitates the reaction. Carbon tetrachloride, chloroform or some similar solvent is also used. It is necessary that the process be carried out in a vessel which will not be attacked by the product, such, for example, as porcelain, terra cotta and glass or glass-lined equipment. Modified methods of preparation are outlined in patents 1,382,921 and 1,382,922. Selenium tetrachloride is formed by the action of chlorine and water on selenium. This compound, reacting in equi-molecular proportions with water, produces selenium oxychloride and hydrochloric acid; the latter is driven off by heat leaving the liquid selenium oxychloride. As in the previous patent, carbon tetrachloride is used as a solvent. Still another process of preparation is by means of a reaction between selenium dioxide and water, followed by dehydration with phosphorus pentoxide, calcium chloride or a similar dehydrating agent. Selenium oxychloride is claimed to possess remarkable solvent properties, being capable of dissolving many substances and compounds for which no known solvent has hitherto been discovered. Among the substances which it will dissolve are: Japans, paints, varnishes, rubber (pure or vulcanized), resins, pitch, glues, shellacs and lacquers, waxes, oils, fats, certain metals and oxides, salts and phenolic condensation products (including the infusible and so-called insoluble products). In patent 1,385,081 it is pointed out that selenium oxychloride is a solvent for the oxides of molybdenum, selenium, arsenic and vanadium, but that it will not dissolve the oxides of titanium, tungsten, zirconium, columbium and tantalum. Hence it is possible by this selective solvent action to separate various mixtures of the soluble and insoluble materials. Selenium oxychloride will react with various oils and greases to form waterproof, rubber-like compounds which may be used as rubber substitutes for certain purposes. (1,382,920, 1,382,921, 1,382,922, issued June 28, 1921, and 1,385,081, July 19, 1921.)

Recovery of Soluble Constituents From Furnace Fumes.—A process claimed to be an improvement on the usual methods for the electrical precipitation of fume or dust has been patented by Harry V. Welch, assignor to International Precipitation Co., of Los Angeles, Cal. It is proposed to supply water to the inside surfaces of the treater flues in order to carry away deposited material and to maintain smooth electrode surfaces. The water is used in a cyclic manner and is heated by waste heat from the furnaces. The operation of the process can perhaps be best understood by consulting the accompanying diagram.

The hot gases coming, for example, from a cement kiln or kilns, and carrying dust and fume containing potash as

a constituent, are conducted through flue 2 to the upper header 7 of the first set of treater flues and passed downwardly through said treater flues into the lower header 8 and then up through the connecting flue 30 and down through the treater flues of the second set, in which they are discharged through flue 31 to the outlet 32. In passing down through the flues 6, the gases are subjected to the action of an electrical field produced between the discharge electrodes 19 and the inside surfaces of the flues 6. These surfaces are kept wet or flushed by streams of water flowing from the nozzles 36 and the body or sheet of water flowing in this manner on the inside surfaces of the flues. High tension current, either direct or alternating, is supplied for maintaining a sufficiently high potential difference between the discharge electrodes and the flues 6 constituting the collecting electrodes. The effect of the electrical field is to cause precipitation of suspended matter, including dust or fumes in the gases, on the body or sheet of liquid flowing down the walls of the flues, this precipitating action being especially effective when the electrodes are charged by a substantially unidirectional current produced, for example, in the manner set forth in the patent of F. G. Cottrell (No. 895,729, dated Aug. 11, 1908). By maintaining a continuously flowing stream of water on the inside of each treater flue, accumulation of any solid material on the walls of such flue is prevented, and a substantially smooth surface free from projections tending to develop discharge from the collecting electrodes is maintained irrespective of the nature of the material being precipitated. This is of especial advantage in precipitating dust or fume, such as cement kiln fume, containing a comparatively high proportion of potassium salts, which would otherwise tend to form a poorly conducting deposit, interfering seriously with precipitation. By thus maintaining the collecting electrodes in condition of maximum effectiveness, it is possible to increase the velocity of the precipitating action and correspondingly increase the rate of flow of gas through the apparatus, with the result that the dust precipitating capacity of a plant of given size is increased to a considerable extent. (1,382,037; June 21, 1921.)

Acid-Resisting Aluminum Alloy.—An alloy particularly suited for resisting the corrosion of nitric acid and nitrate derivatives, such as picric acid, is prepared from purified aluminum and lead in the following proportion: Aluminum, 89 to 94 per cent; lead, 5 to 10 per cent, and 1 to 2 per cent of some oxidizing material such as metallic magnesium. The finished alloy is said to be characterized by increased density and ability to withstand high pressure and corrosion. (1,385,223; Foster Milliken, of Lawrence, N. Y., assignor to Foster Milliken, S. Fullerton Weaver and James M. Repplier, as trustees; July 19, 1921.)

APPARATUS FOR RECOVERY OF SOLUBLE CONSTITUENTS FROM FURNACE FUMES

Current Events

in the Chemical and Metallurgical Industries

Another Muscle Shoals Offer

Details of the offer of C. E. James, of Chattanooga, Tenn., to take over the Muscle Shoals water-power project and the nitrate plants have been given out by the War Department. The following constitutes the entire contents of two letters addressed by Mr. James to the Secretary of War:

First. I will pay for the general plants, land and material at Muscle Shoals, Sheffield, Ala., \$5,000,000.

Second. For rent on Wilson Dam and Dam No. 3 I would pay the following amounts for 97-year lease:

- \$1.00 per annum average horsepower first year
- 1.50 per annum average horsepower second year
- 2.00 per annum average horsepower third year
- 2.50 per annum average horsepower fourth year
- 3.00 per annum average horsepower fifth year
- 3.50 per annum average horsepower sixth year
- 4.50 per annum average horsepower seventh year
- 5.50 per annum average horsepower eighth year
- 6.50 per annum average horsepower ninth year and thereafter

All taxes on Government property and equipment to be paid by the Government.

I would not ask the Government to guarantee any specified amount of power; I would want them to put in the electric equipment capable of producing 400,000 hp.

If the Government put in additional dams above Muscle Shoals in the Tennessee River to aid navigation all the way to Chattanooga to a boating stage of 9 ft., and 6 ft. Chattanooga to Knoxville, the horsepower would run to 800,000 at Muscle Shoals. If so, the Government would receive rental on 800,000 hp., the Government to have the right to equip the plant to 800,000 hp., if it decided to do so, I to take the increased power as produced at above rates.

The concrete foundations in dams ought to be made capable of installing a total of 800,000 hp. machinery, but only install 400,000 hp. now, Government to have, free, 300 hp. current to operate lock gates.

I would operate nitrate plants for fertilizers on a basis of 8 per cent profit, and keep in good condition Plant No. 2, subject to be turned over to the Government in case of emergency.

I would like to have the option, if my proposition is accepted, but not to be embodied in contract, the right to build a high dam for power and storage in the Clinch River at some point near Kingston, Tenn., so as to increase the flow of water at Muscle Shoals, and also to take care of loss of current on wire line, and make the electric current more regular between Muscle Shoals and Kingston, Tenn.

FORD'S MUSCLE SHOALS PLAN DISCUSSED

During a conference with engineers representing Henry Ford the Secretary of War requested that the Ford engineers and the Army engineers harmonize their views as to the amount of money necessary to complete the dam. He also called upon the Ford engineers for the details of their plan for converting Nitrate Plant No. 2 into a fertilizer factory. W. B. Mayo, of Mr. Ford's engineering staff, told the Washington correspondent of CHEMICAL & METALLURGICAL ENGINEERING that the conference was informal and preliminary and that, at the proper time, Mr. Ford will be glad to accept the invitation of Secretary Weeks to come to Washington.

To Study Light Alloys

As a result of a co-operative agreement entered into by the Bureau of Mines with a large manufacturer of scientific instruments, the bureau has been enabled to undertake a much more comprehensive investigation of the alloys used particularly in the manufacture of instruments of precision. The study is to cover a considerable number of the light alloys which are being or may be used for that purpose. The experiments will be conducted by R. J. Anderson at the Pittsburgh experiment station.

Industrial Relations Association to Meet in New York

The annual convention of the Industrial Relations Association of America will be held at the Waldorf-Astoria, Fifth Ave. and Thirty-fourth St., New York City, Nov. 1, 2, 3, 4 and 5. The following preliminary program is announced:

TUESDAY, NOV. 1

- 1 p.m. Registration begins.
- 2 p.m. Round tables and sectional meetings.
- 5:45 p.m. Get-together dinner. Opening address, followed by five leading industrial representatives who will outline in ten-minute talks the most outstanding experiences in the industrial relations activities of their companies during the last year.

WEDNESDAY, NOV. 2

- 10 a.m. Business conditions.
- 2 p.m. Sound employment practice.
- 2:30 p.m. Essential labor statistics and their uses.
- 3 p.m. Industrial relations department costs.
- 3:45 p.m. Round tables.

THURSDAY, NOV. 3

- 10 a.m. Determination of wage rates.
- 12:45 p.m. Luncheon meeting. Business session, I.R.A.A.
- 2:30 p.m. Unemployment.
- 4 p.m. Fundamental principles of human relations in industry.

FRIDAY NOV. 4

Joint sessions with the Academy of Political Science in the City of New York, the general theme being "Constructive Experiment in Industrial Co-operation Between Employers and Employees."

Morning session at Town Hall. Personnel work and co-operation within industrial plants.

Afternoon session at Hotel Astor. Co-operation within separate industries.

Evening session and banquet at Hotel Astor.

SATURDAY, NOV. 5

Morning session at Hotel Astor. Industrial relations in governmental employment or departments and in financial institutions.

Afternoon session at Hotel Astor. Governmental and other organized counsel and information to promote better industrial relations.

American Mining Congress to Meet in Chicago

The twenty-fourth annual convention of the American Mining Congress will meet in Chicago, Oct. 17 to 22, with headquarters at the Congress Hotel. Special attention will be given to the following topics covering different phases of the mining industry: The railroads and the mining industry; co-operative effort and government regulation; standardization; the gold problem; increased use of metal products; taxation; the coal industry; national petroleum conference; educational conference; an American foreign mineral policy.

In conjunction with the convention, the National Exposition of Mines and Mining Equipment will be held at the Coliseum.

Superpower Report Almost Ready

The superpower report made under the direction of the U. S. Geological Survey now is in proof form and probably will be released for publication Oct. 1.

Portland Cement Output Increases in August

Production and shipments of portland cement in the United States continued to increase during August, 1921, and according to available statistics scored new high records for that month. The August production exceeded the average for August, 1917-1921, by about 15 per cent. Production for the first eight months of 1921 was about 99 per cent of the quantity produced during the corresponding period of 1920 and exceeded the average for the first eight months of 1917 to 1921 by about 8.5 per cent.

These statistics, prepared by Ernest F. Burchard, of the United States Geological Survey, and tabulated in the accompanying table, are based mainly on reports from producers of portland cement and in part on estimated data. They indicate that the present demand for cement is greater than might be expected in comparison with that for other mineral commodities, and that in the face of many handicaps to production supply is nearly keeping pace with demand at the height of the construction season.

CEMENT STATISTICS, 1921

Month	Production, Bbl.	Shipments, Bbl.	Stocks at End of Month Bbl.
January.....	4,098,000	2,539,000	10,300,000

To Use Chemical Agents in Alabama Tests

Tests with chemical agents will be made during the maneuvers that are expected to result in the sinking of the U.S.S. Alabama. Chemical bombs are to be tried out in the preliminary tests. Eight 50-lb. bombs charged with tear gas are to be dropped with the idea of gathering data as to the probable effectiveness of this type of bomb on a battleship. In similar manner, phosphorus and smoke bombs are to be dropped on the obsolete war vessel. One of the objects of the test is to determine the effect of smoke bombs in concealing the attack of aircraft and of the effect of white phosphorus clouds in neutralizing anti-aircraft elements.

The board of observers is to consist of three Air Service officers, two Chemical Warfare Service officers and two Ordnance officers.

In addition, there are to be night attacks, in which there will be demonstrated the tactical effectiveness of flares in illuminating a sea area under conditions simulating those of battle. The effect of white phosphorus in outlining sea-craft at night is to be studied to determine if they can be outlined with sufficient distinctness to permit accurate attacks.

T.A.P.P.I. Notes

As noted in our last issue, the executive committee of the Technical Association of the Pulp and Paper Industry has voted to cancel the scheduled joint fall meeting of T.A.P.P.I. and the American Pulp and Paper Mill Superintendents Association. However, the committee on service to members of T.A.P.P.I., of which Fred C. Clark is chairman, is hopeful of obtaining for early publication in the trade periodicals all reports of committees and papers that would ordinarily have been presented at the joint fall meeting. As one of the steps in giving improved service to members, Mr. Clark's committee has issued a questionnaire which members are asked to check according to instructions, and return to the secretary's office without delay.

REDUCTION IN DUES

The annual dues of active and associate members of T.A.P.P.I. will be reduced to \$15. After voting unanimously in favor of this, the executive committee of the association instructed the secretary-treasurer to bill active and associate members for next year's dues at \$15, instead of \$25. This action was taken pending its ratification by the association at the next annual meeting, which, it is believed, will be unanimous.

U. S. Urged to Concentrate on Lighter-Than-Air Development

Based partly on the fact that the United States possesses helium resources, the National Advisory Committee for Aeronautics in a letter to the Secretary of the Navy urges that the United States undertake a more intensive development of lighter-than-air craft. In the letter Joseph S. Ames, chairman of the executive committee of the organization, points out that Germany persisted in her early efforts to develop Zeppelins and refused to be discouraged by failures, with the result that such airships served that country with effect in time of war. It is pointed out that the use of hydrogen in the ZR-2 was a contributing cause to the great loss of life. The fact that the United States possesses large helium resources is given as one of the reasons why lighter-than-air craft probably could be developed more successfully in America than in any other country.

Foreign Markets for Scientific Apparatus

American manufacturers who are desirous of engaging in the export trade will find considerable information of value in a publication of the Department of Commerce on foreign markets for scientific apparatus. It comprises contributions from our Consuls and Vice-Consuls in Argentina, Australia, Belgium, China, India, France, Egypt, Spain and Switzerland. Statistics are given on the origin of imports of scientific instruments and apparatus into these countries. Considerable information of a trade and industrial nature is also given.

Association of Chemical Plant Equipment Manufacturers

At a meeting of representatives of manufacturers of chemical plant equipment at the Chemists' Club, New York, on Saturday, Sept. 17, it was decided to form an Association of Chemical Plant Equipment Manufacturers. The object of this association is to further various interests of these manufacturers, which, it is believed, can be promoted more satisfactorily by action as a group rather than as individuals.

The organization committee consists of J. George Lehman, chairman, Bethlehem Foundry & Machine Co.; Paul O. Abbé, Paul O. Abbé, Inc.; A. A. Holmes, E. B. Badger & Sons; Dr. C. H. Kimberly, Schutte & Koerting Co.; P. C. Kingsbury, General Ceramics Co.

Civil Service Examination

The United States Civil Service Commission announces an open competitive examination for associate metallurgist (qualified in foundry practice). Vacancies in the Bureau of Standards, Washington, D. C., at \$2,000 to \$3,000 a year, and in positions requiring similar qualifications, at these or higher or lower salaries, will be filled from this examination. Applicants should apply on Form 2118 before Oct. 11.

Book Reviews

A DICTIONARY OF APPLIED CHEMISTRY. By Sir Edward Thorpe, assisted by eminent contributors. Revised and Enlarged Edition. Vol. I, A-Calcium. 752 pp., illustrated. New York and London: Longmans, Green & Co. Price, \$20.

For over thirty years Thorpe's Dictionary has enjoyed the reputation of being the single standard reference book of chemical industry in all English-speaking countries. No other work has ever approached it for thorough, accurate and comprehensive information on industrial chemistry. Several times since the dictionary was first issued the editor and publisher have recognized the necessity for revising the work in order to keep pace with the growth and progressive advance of the science. Each new edition has improved and materially expanded its predecessor and has recorded the

increasing number of developments in the application of chemistry to industry.

During the nine years which have elapsed since the publication of the first volume of the previous edition, tremendous and unprecedented expansion has occurred in the chemical industry of all countries, and there is an evident need for a careful survey and critical summary of this progress. The late war stimulated the application of pure science. Many new products have been developed and many old products have been made by new or improved processes. It is too soon to judge of the permanency of some of these changes perhaps, but it is obvious that many of them represent real and substantial progress. In glancing over the present volume, in a cursory way, to be sure, it is interesting to note the number of these developments which have been recognized and accredited by the authors.

One of the first of the major subjects is the article on Acetic Acid, a section of which has rightfully been devoted to a discussion of the synthesis from acetylene. No mention is made, however, of the commercial developments such as those found in Canada, France and Switzerland. In what appears to be a rather inadequate treatment of Acetone, it is surprising to note that the more modern methods of preparation have not been recognized. The fermentation process and the production from acetylene, both processes which were used on a large scale during the war, are not discussed. Under the subject of Alcohol there is reference to the synthesis from acetylene in Germany and also to the preparation from wood by the Classen process which has been tried out in the United States. However, the development in Great Britain of a process of preparing alcohol from ethylene is apparently passed over without mention. An important contribution to the new edition is the article on Aldehyde. Here we find our references to the synthesis of acetic acid and acetone which we have previously looked for under the names of the respective products. This leads us to point out an objection, or rather an apparently inherent fault of the Dictionary or in fact to any other work of similar arrangement. A simple alphabetical presentation of the subject matter, without abundant (and bothersome) cross-references, often makes it extremely difficult to find the information one desires. A comprehensive index would certainly be a worth-while improvement to the new edition.

There has been notable revision and expansion in the reviews covering Alizarin Dyes and Ammonia. The new anæsthetics developed by the war are recorded. The section dealing with Analysis has been revised and slightly enlarged, and this brings to the reviewer's mind the question of whether such an extended treatise (104 pp.) is not out of place in a dictionary on applied chemistry. It would appear to the reviewer that this space could be better used in emphasizing chemical engineering applications and equipment, a subject in which is treated far too inadequately in most text books. A new article on Organic Arsenicals is a worthy addition to the volume. It is also to be noted that Azo Dyes have been given a somewhat extended treatment to very good advantage.

The reviewer was rather surprised to find that seven pages had been devoted to Bone Oil and the theoretical discussion of its constitution. Cutting the article on Brewing to half the size of the former contribution will probably be somewhat disappointing to the many American readers who have been conducting home experiments in this ancient art. Butyl Alcohol, however, has come to occupy a position of considerable industrial importance and there is no mention of its preparation by the fermentation process or its important application as a solvent.

With this final comment on the contents of the book, the reviewer is tempted to risk, as his opinion, one general fault of the work, past and present editions included. There is an evident failure to recognize American practice in chemical engineering. The emphasis is placed first on the British and then on the Continental methods, while there is seldom a reference to the processes used in the United States. It is natural, of course, that the English work should deal with England, but we believe that many American readers will join us in our rather selfish desire to find an occasional reference to our own way of doing things.

However, it is not our intention to be fault-finding and

we have previously referred to the work as "the greatest contribution in English to the literature of applied chemistry." The remaining volumes will be awaited with interest, and it is hoped that they too will record the same improvement that has characterized the first volume of this splendid work.

S. D. KIRKPATRICK.

Personal

Dr. E. M. A. CHANDLER has resigned his position with the Dicks-David Dye Co., Chicago Heights, Ill., to take employment with the Industrial Chemical Laboratory Co., at Hammond, Ind., manufacturer of dye intermediates.

Dr. V. H. GOTTSCHALK, formerly director of research for the American Cotton Oil Co., has accepted a position in the metallurgical engineering department of the Western Electric Co., Chicago, Ill.

WILLIAM MYERS has been engaged by the Bureau of Mines as a member of its non-metals investigation staff. He will be stationed in Washington.

TUDOR S. RODGERS has resigned from the Tecopa Consolidated Mining Co., Inyo County, California, where he was chief chemist and assistant mill superintendent, and is now engaged in the practice of law, with offices in Salt Lake City, Utah.

GEORGE OTIS SMITH, director of the U. S. Geological Survey, will address the annual meeting of the New York State Oil Producers' Association at Olean, N. Y., on Sept. 31. His subject will be "The Real Value of Oil." Dr. Smith has accepted an invitation to address the General Staff College of the Army on Oct. 5 on "Strategy of Minerals." Later in the course he will address the class on "Superpower."

L. J. WALDBAUER has resigned his instructorship at the University of Maine to accept a demonstratorship at McGill University, Montreal, Canada.

J. E. WALTERS, F. W. SCHROEDER and FRANK PORTER, chemists who have been on duty at the helium plant at Petrolia, Tex., have been transferred to Washington, where they have been added to the force at the cryogenic laboratory.

W. M. WEIGEL, of the chemical division of the Bureau of Mines, who has been studying deposits of filler materials in the Southwest, will now visit Eastern plants that are utilizing these materials. This work is being done in connection with the general study of filler problems being made by the bureau.

EDWIN D. WINKWORTH has been named executive vice-president for the Solvay Process Co., in full charge of management of the parent concern of all Solvay interests.

Obituary

Captain ANTHONY F. LUCAS, who was responsible for the famous Lucas gusher at Spindle Top, the pioneer of the Gulf Coast oil development, died in Washington on Sept. 2. Captain Lucas was born in Spalatro, Dalmatia, Austria, in 1855, and possessed all the kindness and sympathy for others characteristic of the Montenegrin race from which he was descended. He did important work on salt, petroleum and sulphur, it being the oil from Spindle Top, used as fuel, which made possible the development of the Frasch system of mining sulphur. His discoveries had an immense bearing on the development of modern technology, the raw mineral products discovered by him being the incentive for a great deal of engineering progress. He avoided publicity and ceremony and was content with doing for the sake of doing. His life work is catalogued in "Pioneering the Gulf Coast," by R. S. McBeth.

Review of the Industrial Chemical Market Since the Beginning of 1921

THE first eight months of the year have been a mighty disappointment to those who were of the opinion that January, 1921, would see the beginning of a marked revival in the general list. Everyone hoped for the best, but in reality looked for the worst and got the fulfillment of his expectations. The year so far has been filled with more business reverses than have ever before been experienced by the chemical industry, and it is only within the past few weeks that the rays of hope have been penetrating through the edges of passing dark clouds.

There has been some improvement in 1921 when conditions are compared with the acute slump in values during 1920. Conditions have improved steadily since the first of the year inasmuch as the rate of loss in values has been steadily diminishing. During the period of the war and immediately after the signing of the armistice spot quotations through speculation rose 300 to 500 per cent above the 1913-1914 normal values. At the beginning of the war the entire list was about 75 per cent above the 1914 average. The loss so far this year has been somewhat around 25 per cent of the inflated figure, bringing an average of industrial chemical values today to about 50 per cent above pre-war figures. Although there are quite a few items that are selling at figures which are actually lower than the pre-war price, the majority of chemicals still stand far above 1914 prices.

THE EXPORT SITUATION

The American chemical industry has suffered greatly during the current year, as far as export business is concerned. European rates of exchange have just about driven the American exporter out of the running. South America has welcomed German commercial representatives aided by a very cheap mark, and has returned to its former source of chemical products. Japan until recently has done only a small amount of chemical business. The Germans are attempting to win back this field and have dumped a large amount of products at much lower than American costs. It seems, however, that the Japanese are looking for American chemicals and have materialized this desire by placing numerous large orders in the market during the past few weeks.

THE IMPORT SITUATION

The chemical import business has progressed markedly in the face of the many adverse conditions. Here and there new houses are being organized to handle European imports. The depreciated mark and franc have given the foreign manufacturer an exceptional opportunity to ship goods into this market at prices with which American producers have been absolutely unable to compete. The biggest portion of the chemical business which has passed in the market since the beginning of the year has been in imported goods. American manufacturers have been looking on, awaiting some action from Congress which will give them a chance to do some business again. While the emergency tariff has kept out all synthetic and coal-tar chemicals, other products have been permitted to flood the market and have been the chief cause in bringing prices down. It is, therefore, quite evident that the export and import situations have been steadily depressing the American manufacturer, making it an impossibility to market his products at prices compatible with American costs of production.

THE TARIFF QUESTION

The apparent recovery of the German chemical export market, as evidenced by the heavy shipments of potash products to this market and the legislative situation in Washington, has held the center of the domestic chemical stage. Between the dye license clause and the Fordney tariff bill, the chemical industry as a whole has had little peace. The chemical market has been split in many ways by the legislative situation. Manufacturers have been strong in their desire for adequate protection in the form

of a high tariff, while opposed to this position stand the large consuming industries and the chemical importers. The frequent large shipments of German material at extremely low prices, especially potash salts, prussiates and bromides, combined with heavy imports of French and British soda ash, have been the big feature in the American producers' fight for protection. The consensus among leading manufacturers is that no definite action on these bills will be taken before some time in December. The chemical and dye industries, in the meantime, have been given protection to some degree by an extension of the emergency tariff to Nov. 27.

THE SODA SITUATION

Prices in the soda industry have not been affected so acutely by importations of foreign goods, because of the fact that imports have come from countries whose exchanges are not so depreciated as is that of Germany. Soda ash imports have come in large quantities chiefly from England and to some degree from France. Caustic soda has not gone below \$3.80 per 100 lb. in the resale market and imports have not been at all noticeable. The goods that have arrived in this country have been offered below those at which American makers have offered, but imports have been closely held, so that no excess above consumers' requirements have come into the market to force further decline in quotations. The practice of selling the goods before ordering their import has in no doubt saved the alkali industry from any serious injury. Scarcely an item in the heavy chemical list, with the exception of the heavy acids, has failed to feel the effect of the low exchange and low manufacturing costs abroad. Alums, fluorides, ammonium chloride and prussiates have been subject to the same influences and the result has been that producers of these products have been forced to close their plants or greatly reduce their output.

THE POTASH INDUSTRY

The sharp decline in the potash market was due to the Scandinavian countries, which reshipped large quantities of caustic potash that had been sent to them by American producers in 1919 and 1920. This material was shipped to them with the hope that the peace settlement would leave Germany without potash and that as soon as trade was resumed an open market would be found for it in countries which had previously depended principally on Germany as their source of supply. In spite of the fact that France assumed control of the greater portion of Alsatian deposits, German prices began to slump so rapidly that American manufacturers were forced to close their plants and center their hopes in Congress. Holders of American stocks of potash abroad became convinced that their plans had met utter failure and returned large portions of it to the New York market to be sold as quickly as possible. From that time until a few weeks ago prices slumped tremendously until this reshipped caustic had been absorbed. Prices worked themselves down to as low as 4½c. per lb. During this time crude muriate of potash, which was held at \$2.40 per unit during the summer of 1920, was forced down to the present price of 85c. per unit by the production of the Germans and French, who were endeavoring to place themselves on a better financial footing. The strong competition for the American market has put the domestic producers of crude potash salts under as heavy a handicap as the producers of other potash salts. The heavy freight charges from the western producing districts, together with the more expensive methods of obtaining potash from low-grade ores which it has been necessary to employ as compared with the ordinary procedure required by European salt deposits, have placed the crude potash producers in a very unhealthy position. It is highly questionable if the proposed duties will relieve the situation to any material degree. Manufacturers of potash compounds from this crude material have been forced to use imported raw material, and even then have found it impossible to compete with foreign goods. Their condition is considered more serious when it is to be remembered that the proposed duty on their products is equivalent only to the raw material duty urged to protect the crude potash producers.

Potash Production in Alsace

Reports from Strassburg state that the output of the Alsatian potash mines will be doubled in October, according to a Reuter cable from Paris. It is probable that the monthly production of potassium chloride in 1922 will average about 10,000 tons, a large proportion of which will be available for export.

Hydro-Electric Inspection Tour Planned by Engineering Society of Buffalo

The Engineering Society of Buffalo has planned a novel and interesting meeting for Saturday, Oct. 8. On that date the members of the society will meet at noon and travel by automobile to Niagara Falls, Ont., where they will be taken on an inspection tour of the Chippewa-Queens-town hydro-electric development which is now being completed.

This tour will be conducted by the men in charge of the electrical, hydraulic and construction branches of the work. After the tour the party will return to Buffalo for dinner at the University Club, where addresses will be given by the engineers in charge of the development.

The Rochester Engineering Society and the Niagara Peninsula branch of the Engineering Society of Canada have been invited to accompany the Buffalo Society on this trip.

Chemical Companies Organized

During the month of August, a total of thirty-seven new companies in the chemical industries was organized, with authorized capital of \$50,000 or greater. The combined authorized capital of the new concerns totaled \$15,495,000, representing the largest monthly total for new companies in this line of business since January last, and indicated a striking contrast with the aggregate for the preceding month of July, which stood at \$3,265,000. In August, 1920, the indicated capitalization of new chemical companies was \$36,715,000. During the first eight months of the present year, January-August, inclusive, chemical organizations with a combined capitalization of \$84,385,000 have been formed, as compared with \$167,922,000 for the corresponding period of 1920.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Sept. 26, 1921.

Business is showing a decided improvement throughout the list as consumers become more confident of present price levels, and while the market is still somewhat irregular, the movement of stocks is rapidly increasing. The demand, while chiefly from domestic consumers, embraces a moderate amount of foreign requirements. South American countries and Mexico are inquiring for miscellaneous chemicals and sales have been noted in various quarters. Soapmakers have been among the largest purchasers, while glass factories, tanneries, paper and textile mills have all shown a marked improvement in covering their chemical necessities. Quite a number of firms report that business so far this month has been better than during the entire month of August, which was considered the best month since the beginning of the depression. There has been a tendency in several instances to increase the size of commitments and more carlot transactions have been noted in the heavy chemicals. The market, in general, is showing considerable resistance around prevailing levels and there were several instances of net advances at the close of the week.

Solid caustic soda was one of the large items which recorded a firmer tone in the final trading. Advancing prices on caustic potash also featured the week's market. This chemical is sharply higher on diminished spot stocks, and while the foreign markets are showing firmness, it is believed that arrivals will bring prices back to slightly

lower levels. Ammonium sulphate is higher both at the works and for export. Sodium nitrate is firmer. Bichromate of soda was another chemical that displayed a splendid tone on spot. The recent advance in prussiate of soda has been well maintained.

Importations of German chemicals have freely continued. Large arrivals of potash products are noted from Hamburg. These, however, did not have any marked depressing influence on values, as it is understood that a large portion of this material was sold to arrive. There have not been any recent importations of foreign caustic soda and soda ash. The price of domestic ash seems low enough to satisfy domestic consumers and they are not desirous of meddling with foreign goods at the present time.

Outside developments during the past week have been of a highly favorable character. The steel industry has shown a noteworthy improvement so far this month. Large steel companies have announced the reopening of their plants on full-time operation and have advanced prices, which have helped decidedly in stimulating new business. The textile industry is gradually forging ahead, while the paper mills are steadily recovering from their adverse conditions noted earlier in the year.

CHEMICALS

Spot *caustic potash* was advanced and the market closed in a firm condition with relatively little stock offered. Shipment prices from Germany have been advanced and it is doubtful if better than 5½c. per lb. would be accepted on the 88-92 per cent. Dealers quote the spot market at 5½c. per lb. Buyers have not been desirous of following the advance, but it looks as though they will soon be reconciled to the higher trading level. Imported *chlorate of potash* is quoted at 7c. per lb. on spot and 6½c. afloat. Shipments were quoted at 5½@5¾c. per lb., c.i.f. New York. Domestic material continued unchanged at 12c. per lb., f.o.b. works. Spot *bicarbonate of soda* is offered by dealers at \$2.40 per 100 lb. packed in barrels and at \$2.75 per 100 lb. in kegs. At the works producers quote 2c. per lb. for barrels and 2¼c. for kegs. A fair inquiry has featured the market for this material, but there has been no unusual change in trading. Closing prices for solid *caustic soda* record a net advance for the week. The demand for this chemical is gradually increasing, while supplies of standard brands are relatively light in second hands. Prices have ranged from \$3.90 to \$4.05 per 100 lb. during the past week and the final quotation for standard goods was 4c. per lb. Sales have included the wants of both foreign and domestic consumers and the movement is considered quite satisfactory by prominent dealers. Market prices on *nitrate of soda* have been a trifle easier, with sellers at 6¾@7c. per lb., depending upon the quantity. The inquiry continues rather light, with competition somewhat keener for the light passing business. Higher prices have been established for *prussiate of soda*, ex-store. The demand at intervals was active, and while small lots commanded the most attention, the aggregate business for the week was well up to the standard. Most of the business went through at 12¾@13c. per lb. Spot prices on *soda ash* have continued firm with an advancing tendency. Large dealers quoted the market for single bags at \$2.10@\$2.15 per 100 lb. and reported sales at these figures depending upon the quantity involved. Several transactions in barrels were reported at \$2.45@\$2.50 per 100 lb. Sales of *bleaching powder* in large drums are reported at 2¼c. per lb., f.o.b. works. Sales of imported material are noted at 2c. per lb., ex-dock New York, duty paid. Shipments of foreign material are quoted at \$1.90 per 100 lb., and this price was named for goods for arrival in about a week. Several carload lots have changed hands during the week and a good inquiry from the consuming trade was reported from leading makers.

Large sellers of *oxalic acid* quote the market firm at 16½c. per lb. Small lots could probably be purchased in some directions a shade under this figure. The call is mostly for small quantities. At the works 16c. per lb. was named. First-hand sales of *phosphate of soda* are reported on the basis of 4½c. per lb. for the commercial. The same price was named for *bisodium phosphate*. The U.S.P. variety is quoted by producers at 7½c. per lb. *Copperas* manufacturers quote \$18 per ton in bags and up to \$23 per ton in barrels

f.o.b. works in large lots. Domestic makers of *strontium nitrate* quote 18@20c. per lb., although it is possible to do 12@12½c. through importers.

COAL-TAR PRODUCTS

A decided improvement in the sales of intermediates has been made during the past week. The general air of uncertainty, caused by the tariff delay, which has hung over the trade for the past few months, is gradually being dispelled and is giving way to a firm conviction that adequate protection will be accorded to the industry. Consumers in many cases are abandoning hand-to-mouth operations and are placing contracts for good quantities. Resale lots of cheap material are cleaned out in most cases except where manufacturers are using resellers to cover their own unloading operations which have had to go on at sacrifices. For the first time in many months optimism is shown in producing quarters and even those formerly pessimistic are stating that the turn has come. Prices all around are holding steady, but some slight reductions in intermediates were made by makers during the week. Moderate selling of *naphthalene flakes* is going on at 6½@6¾c. per lb. for prime quality goods. Supplies are plentiful and competition for business is keen. First hands quote *aniline oil* at 20c. per lb., but actual sales have been made at 18@18½c. Some resale goods are still obtainable at 17½c. The demand shows considerable improvement and sellers generally are steadier in their views. Most *beta naphthol* sales have been put through at 34c. per lb. First hands continue to quote 40c. per lb., but resale lots are obtainable at 32c. Buying has been moderately active. Sales of *ortho-toluidine* were made at 21c. per lb. and some holders ask up to 25c. The demand is fair. Rumors of lower prices are heard on *alpha-naphthalamine* and there is little doubt that firm business in quantity would bring concessions from makers. Second hands quote from 33@35c. per lb.

WAXES

Importers of *African crude beeswax* report a good volume of business at steady prices. For spot material the market held around 15c. per lb., but on futures as low as 13½c. has been named. *Brazilian crude* was more or less nominal at 21c. per lb. and upward, depending upon seller and color. *White refined wax* was quoted at 36@42c. per lb. The situation on *carnauba wax* presented nothing new, prices holding in sympathy with primary markets. The lower grades were in the best demand and prices for the No. 3 chalky closed at 15@15½c. per lb., with the No. 3 North Country held at 25c. per lb. Holders' views on *Japan wax* were firm due to the recent rise in the cost of import, but the advance has checked buying and prices at the close were more or less nominal at 23@25c. per lb., depending upon the seller and quantity. A moderate improvement was reported in the export demand for *paraffine wax*, but with offerings liberal, prices failed to move upward. Scale wax closed nominally at 1½@2c. per lb., earload basis, f.o.b. works. Export of both crude and refined paraffine for the month of July amounted to 20,876,244 lb., as against 23,583,766 lb. for July a year ago. Exports for the seven months ended with July amounted to 112,101,773 lb., compared with 236,674,790 lb. for the same period a year ago and 128,051,891 lb. in 1919.

The Chicago Market

CHICAGO, Sept. 23, 1921.

All quarters report an increase in business on the general list of industrial chemicals during the past two weeks. Dealers are quite optimistic over the outlook and report conditions as very satisfactory. Prices are firm and holders show no disposition to shade their regular quotations. Stocks are getting low in some quarters, which is a factor to be considered in the firmness of the local market.

INDUSTRIAL CHEMICALS

There is a good demand for *caustic soda* in both the ground and solid forms and prices are very firm. The ground 76 per cent is bringing \$4.65@\$4.80 per 100 lb., according to quantity and holder, and the solid 76 per cent \$4.25@\$4.37½. *Soda ash* is moving in a very fair way and the price is firm and unchanged at \$2.60 per 100 lb. for material in coopeage. *Ammonium chloride* is rather quiet

with ample supplies of the white granular available at 7½c. per lb. *Sulphate of ammonia* has shown a decided firmer tendency during the last few days and it is doubtful if supplies could be had at less than 3¼c. per lb. *Potash alum* is reported to be moving in a fair way at 6c. per lb. for the granulated in barrels. *Aluminum sulphate* is rather scarce and small lots were bringing 2½c. per lb. for the ground iron-free. There is a good demand for *carbon bisulphide* at 7c. and *carbon tetrachloride* at 11c. per lb. Business in *formaldehyde* is rather dull, with dealers quoting 12@12½c. per lb. for single barrels. *Glycerine* is still quiet, with ample supplies of the c.p. material offered at 14c. per lb. Several small sales of *iron sulphate* were noted at 1¼c. per lb.

There is a very good demand for *litharge*, which is quoted by producers at 7½c. per lb. in kegs. *Lead acetate* is said to be selling at a rather brisk rate at 13@13½c. per lb. *Caustic potash* is showing a firmer tendency, with stocks diminishing, and 6½c. per lb. for the 88-92 per cent material was the best offer noted. *Bichromates* are firm as to price and are moving well. *Potash bichromate* is available at 13@13½c. per lb. *Sodium bichromate* on spot is difficult to locate and material to arrive is quoted at 9½c. per lb. There is a fair request for *bicarbonate of soda*, which is firm and unchanged at \$2.60 per 100 lb. *Sodium acetate* is moving in a fair way at 5½@6c. per lb. *Hyposulphite of soda* is in good demand and manufacturers are maintaining the price at \$4.05 per 100 lb. for the pea crystals in barrels. Several large sales were reported on *sodium fluoride* at 11c. per lb., smaller quantities bringing 12c. *Glauber salts* were available at \$1.90 per 100 lb., with a fair movement noted. *Zinc chloride* is in good demand, with prices ranging from 11½c. for the domestic to 9½c. per lb. for the imported.

The list of acids, generally speaking, was maintained as to price. Business in *acetic acid* has shown a decided improvement and prices are firm. The 28 per cent in barrels is quoted at \$2.65@\$2.75 per 100 lb., according to quantity, and the glacial at \$10.25@\$10.75 per 100 lb. *Citric acid* is rather slow, with manufacturers quoting 47½c. per lb. for barrels. It is possible to shade this price a few cents in second hands. *Tartaric acid* is in a similar position, first hands asking 35½c. per lb. for barrels. There is a better movement of *sulphuric acid* and the price is maintained at \$19@\$20 per ton for tank cars, f.o.b. works.

VEGETABLE OILS

A very good movement of *linseed oil* is reported by dealers. The raw oil is quoted at 76c. per gal. and the boiled at 78c.

NAVAL STORES

This branch of the trade has nothing to complain of and business is reported as very good. *Turpentine*, as with other paint materials, is moving very well. Today's quotation is 76c. per gal. for drums. There is also a fair demand for *rosins* with carlots of the WW grade quoted at \$7.50 per 280 lb. and corresponding prices for the other grades.

The Iron and Steel Market

PITTSBURGH, Sept. 23, 1921.

Last week's advance in prices of wire products, \$2 to \$3 a ton, has been followed by an advance of \$5 a ton in sheets. There are cross-currents, as pipe-mill products, including standard steel pipe, line pipe, oil country goods and boiler tubes, have been formally reduced \$8 to \$10 a ton, while to complete the divergence, bars, shapes and plates have been practically unchanged in price for a fortnight.

The steadiness in prices of bars, shapes and plates is a plain fact. These commodities are commonly called the "heavy rolled products" and easily comprise the most important part of the finished-steel market in general. The advances and declines referred to above are facts, but they are not so plain. The sheet and wire advances were preceded by heavy bookings at the old prices. It is no secret that the producers took pains to inform buyers that prices were going to be advanced. On the other hand, the formal reduction in pipe-mill products is not as great as appears by the changes from the published lists of July 7 to those of Sept. 16, for the reason that there had been some shading almost from the time the old lists had been put out.

In standard steel pipe the shading averaged about one-half of the formal reduction now made, while in oil country goods the shading was approximately equal to the formal reduction.

CONTINUOUS DECLINE IN STEEL PRICES ENDED

Declines in steel prices may not be wholly ended, but the continuous decline is over. For the future we shall have slight ups and downs, for while the general decline is over there is no plain indication that a general and continuous advance has succeeded it. One does not know that the advanced prices for sheets, for instance, will be maintained indefinitely, or be followed by other advances. This may or may not be the case.

Steel prices had declined far enough to represent a very decided liquidation. Taking wire and sheets at their former prices, since buyers are covered at those prices, finished steel products by a weighted average are at 33 per cent above their 1913 average, so frequently taken as a basis of comparison. Thus they would stand at 133 according to the system used by the Bureau of Labor, which reports for August 152 as the index number of wholesale commodity prices in general, made up of individual items ranging from farm products at 118 to house-furnishing goods at 230.

Bars, shapes and plates are generally quotable at 1.65c. In some cases mills may obtain a little more, for small or undesirable orders, while particularly desirable orders may go at slight concessions. There is no hint that as low as 1.50c. has been done in a solitary instance in the past fortnight. Weeks ago some buyers set 1.50c. as the price to which bars, shapes and plates should decline in order to be on a stable basis, but at this date, with wire products and sheets having already reacted upward, it seems safe to conclude that if bars, shapes and plates were going to go to 1.50c. they would already have done so. At some time, doubtless, they will sell below 1.50c., but probably not until fundamental items of cost have experienced reductions that are not in immediate prospect.

MILL OPERATIONS

The American Sheet & Tin Plate Co. operated its sheet mills at about 54 per cent last week and scheduled a 70 per cent operation for this week, but the average is likely to be higher. Independent sheet mills recently were operating at about 40 per cent, but are likely to go to an average of 75 per cent or better, disregarding a few plants that are entirely idle. Wire mills are doing better than 50 per cent and pipe mills nearly as well. Bar, shape and plate production is very light and rail production is almost nil, in percentage of actual capacity.

The rate of steel ingot production may be estimated at about 33 per cent, this comparing with an average of 30 per cent in August and a rate just under 20 per cent at the low point, about the middle of July. While demand for wire products, sheets and tubular goods has been improving decidedly, bars, shapes, plates and rails, being heavy products, prevent the production of ingots from showing any great response. The rate of steel production may reach 40 per cent within a short time, but it seems improbable that it will attain 50 per cent at any time this year. Rather strong hopes are entertained for early spring, these hopes being based on a resumption of railroad buying on a fair scale and a decided increase in general construction work.

PIG IRON

Pig iron prices have been well maintained in all districts in the past week and it looks as though prices would tend to advance rather than decline, not on the ground of there being heavy demand, but rather because prices are in most cases below cost of production and the cost of production is not going to experience a decline, by reductions in freight rates, as soon as was expected. The valley market remains quotable at \$20 for bessemer, \$19 to \$20 for basic and \$21 for foundry. Inquiry has been very light, since the recent little spurt in activity, but another movement is expected shortly. The Standard Sanitary Manufacturing Co. has just inquired for 4,000 to 5,000 tons of Northern and Southern iron for fourth quarter delivery to its plant in Pittsburgh, New Brighton and Louisville.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

RICHMOND—The Republic Steel Package Co., 7930 Jones Road, Cleveland, O., has plans nearing completion for the construction of its proposed new plant on property recently acquired at Richmond. A railroad line is being constructed to the site. The initial plant unit will be 1-story, 60 x 300 ft., and will be equipped to give employment to about 100 operatives. S. B. Merry is treasurer.

SAN FRANCISCO—The Western Pipe & Steel Co., 444 Market St., is planning for the early operation of its new works at South San Francisco, comprising the former plant of the Shaw-Batcher Shipbuilding Co. Remodeling work is under way and a number of extensions and improvements will be made, with the installation of equipment for the manufacture of steel pipe, tanks, well casings and kindred products. Employment will be given to about 500 men.

Illinois

HAMILTON—The Champion Coated Paper Co. is completing plans for the construction of a 4-story and basement plant addition on North B St., 35 x 185 ft., estimated to cost about \$50,000. Peter S. Thompson is president.

Kentucky

BOWLING GREEN—The Hillman Syndicate is perfecting plans for the erection of a new local oil refinery, estimated to cost in excess of \$150,000, including equipment.

BOWLING GREEN—E. J. Riggs and associates are organizing a new company to construct and operate an oil-refining plant on local site. The refinery will have an initial daily capacity of about 300 bbl. and is estimated to cost approximately \$125,000.

Maryland

BALTIMORE—The United States Industrial Chemical Co., Fairfield Road, has filed plans for the erection of a 1-story addition to its plant, 42 x 112 ft.

BALTIMORE—The Fleischmann Co., North Ave., will commence operations at once at its new local yeast-manufacturing plant, occupying a large site at Central Ave. and Bank St. The structure with machinery represents an investment of close to \$3,000,000, and forms the third plant of the company in this city.

BALTIMORE—The Cooknut Corp., Lexington and Paca Sts., has awarded a contract to the Charles L. Stockhausen Co., Inc., 33 South Gay St., for the erection of its proposed new plant on Canton St. for the manufacture of lard substitutes and kindred products. The works will consist of a main 4-story and basement factory, 88 x 100 ft., with 1-story extension, 50 x 56 ft. A 1-story machine shop 35 x 50 ft., will also be constructed. The buildings will be of reinforced concrete and are estimated to cost close to \$125,000. W. R. Sprull is president.

Massachusetts

WALTHAM—The Elastoid Fibre Co. has awarded a contract to the H. P. Cummings Cons. Co., Ware, Mass., for the construction of a new 1-story plant on Lexington St., 70 x 180 ft., to be equipped for the manufacture of fiber products.

Minnesota

PAYNESVILLE—The Farmers Mill Co., J. Z. Jerabek, secretary, has awarded a contract to the T. E. Ibberson Co., Corn Exchange Bldg., Minneapolis, Minn., for the erection of its proposed new flour mill. The structure is estimated to cost in excess of \$80,000.

Montana

BUTTE—The Cascade Silver Mines & Mills Co. is planning for the rebuilding of its concentrating plant at Neihart, Mont., recently destroyed by fire. The company will also build a new zinc-smelting plant in the same district.

Nebraska

OMAHA—Fire, Sept. 11, destroyed the plant of the Eckman Chemical Co., 16th St., with loss estimated at about \$60,000. The works will be rebuilt.

New Jersey

HOBOKEN—The White Metal Mfg. Co., Grand St. near Eleventh St., has completed plans and will soon call for bids for the erection of its proposed new plant on Grand St. It will comprise a main 6-story building, with 1-story structure adjoining, 58 x 65 ft., and 136 x 136 ft., to be used for general production. Joseph C. Schaeffer, 11 East Fifty-sixth St., New York, is architect.

BAYONNE—The Standard Oil Co., Twenty-second St., has filed plans for extensions in the tankage department at its local oil refinery to cost about \$115,000.

NEWARK—The Wallington Leather Co., 46 Kent St., has filed plans for the erection of a new 2-story leather-manufacturing plant, estimated to cost about \$22,000.

NEWARK—The Butterworth-Judson Corp., Doremus Ave., manufacturer of chemicals, dyes, etc., is arranging plans for reorganization. It is proposed to form a new company to take over the property and assets of the present corporation, and continue plant operations. The new organization will issue bonds for \$2,600,000, for general financing, operations, extensions, etc.

FLORENCE—The Florence Pipe Foundry is considering the erection of a new 1-story foundry for the manufacture of iron and steel castings. It will be about 40 x 100 ft. C. L. Reeves is superintendent.

MILFORD—The Warren Mfg. Co., manufacturer of paper, has placed all units of its local plant in operation, including three paper-manufacturing machines and subsidiary equipment. Tentative plans are under way for enlargements at the local mill, due to the permanent closing of the company's plant at Riegelsville, Pa. Equipment now at the latter plant will be removed to Milford, as well as certain machinery to the branch mills at Hughesville and Warren Glen.

New York

ENDICOTT—Walter D. Johnson, operating a local leather-manufacturing plant, has had plans prepared for the erection of a 2-story addition, 40 x 100 ft. Construction will be commenced at an early date.

BROOKLYN—Fire recently destroyed a portion of the plant of the Manhattan Shoe Polish Co., 49 Dean St., with loss estimated at about \$40,000.

Ohio

EMPIRE—The Miner Firebrick Co. has resumed operations at its local plant, following a curtailment for many months. The plant will give employment to about 75 operatives for an indefinite period.

REDFORD—Officials of the Owen Tire & Rubber Co. are considering a plan for reorganization of the company. Manton M. Scott has been appointed receiver. The company has assets said to total \$800,000 and liabilities of about \$200,000. Operations at the plant will be continued pending the proposed reorganization.

Pennsylvania

NICHOLSON—Fire, Sept. 9, destroyed the celluloid department and other sections of the plant of the Lackawanna Cutlery Co., with loss estimated at about \$75,000.

PHILADELPHIA—Fire, Sept. 14, destroyed a portion of the Point Breeze oil refinery of the Atlantic Refining Co., with loss estimated at about \$100,000, including oil stills, etc.

South Carolina

LAURENS—The Laurens Brick Co. is planning for the construction of an addition to its plant on the Little River, to increase the daily output from about 30,000 to 40,000 bricks. H. C. Fleming is treasurer and manager.

KNOXVILLE—The Knoxville Fertilizer Co. has plans under way for the erection of a new plant at Vestal, near Knoxville, for the manufacture of commercial fertilizer products. The plant will consist of two main 1-story buildings, 160 x 350 ft. and 100 x 300 ft., respectively, and is estimated to cost about \$300,000, including machinery. The initial works will have a daily output of close to 150 tons. James W. Dean is secretary and treasurer.

Texas

WACO—The Southwestern Portland Cement Co., El Paso, has acquired an extensive tract of property at Waco, comprising about 250 acres of land, and has preliminary plans under way for the erection of a new cement-manufacturing plant on a portion of the site. The initial works will cost about \$1,500,000, including equipment. Carl Leonhardt is president.

THREE RIVERS—The Three Rivers Glass Co., 605 National Bank of Commerce Bldg., San Antonio, is perfecting plans for the erection of its proposed new glass-manufacturing plant at Three Rivers. The company has obtained a site with available high-grade glass sand. The new plant is said to be estimated to cost in excess of \$100,000.

CISCO—The Cisco Clay & Coal Co. has commenced the erection of its proposed new brick-manufacturing plant, to specialize in the production of vitrified paving brick and kindred burned clay products. The plant will have an initial minimum capacity of about 50,000 bricks per day, and is estimated to cost about \$200,000, including equipment. C. B. Bush is president.

DESDEMONA—The Magnolia Petroleum Co. has construction under way on a new casing-head gasoline plant, with initial capacity of about 3,000 gal.

West Virginia

MORGANTOWN—The Star Glass Co. is completing plans for the rebuilding of its local glass-manufacturing plant, recently destroyed by fire. The new works will consist of a main 1-story building, 145 x 500 ft., and two adjoining structures each 50 x 150 ft. A cooper shop and box factory will also be erected, as well as machine shop and other mechanical buildings for general operating and repair service. The new plant is estimated to cost about \$225,000, with machinery. Louis Kauffeld is general manager.

Wisconsin

PORT EDWARDS—The Nekeosa-Edwards Paper Co. is planning for the rebuilding of the portion of its plant, destroyed by fire, Sept. 2.

MILWAUKEE—The Red Star Yeast & Products Co., 79 Buffalo St., will soon commence the erection of a 1-story addition to its plant, 50 x 100 ft., on Twenty-seventh St., estimated to cost about \$15,000.

Wyoming

CASPER—Effective Oct. 1, the Standard Oil Co. of Indiana, Indianapolis, will take over and operate the oil-refining plants of the Midwest Refining Co. at Casper, Graybull and Laramie, Wyo. General expansion in operations is planned. The Midwest company will continue as a producer of crude oil and will operate in the different Wyoming fields.

Ontario

TORONTO—The National Potash Corp., Gravenhurst, Ont., has construction under way on a new plant for the manufacture of glass products. It is expected to have the works ready for service at an early date, with facilities to produce a general line of ware.

TORONTO—The Follansbee Bros. Co., Pittsborough, Pa., is planning for operations at its new local steel plant, now in course of construction, early in October. The plant is being rushed to completion, with double working crews.

Nova Scotia

HALIFAX—Fire, Sept. 12, destroyed a portion of the refining plant of the Imperial Oil Co., at Dartmouth, near Halifax. It will be rebuilt.

Capital Increases, Etc.

THE HIGH FALLS PULP & PAPER Co., High Falls, N. Y., has filed notice of increase in capital from \$150,000 to \$600,000.

THE CORNING FOUNDRY Co., Corning, N. Y., manufacturer of iron and steel castings, etc., has filed notice of dissolution under state laws.

THE INDEPENDENT STARCH Co., 204 Franklin St., New York, N. Y., has filed notice of increase in capital from \$30,000 to \$100,000.

CLARK M. WHITEMORE and EDMUND B. CLARY, Linden, N. J., have been appointed receivers for the Trans-Atlantic Chemical Co., operating a large local plant for the manufacture of chemicals, dyestuffs, etc. The application for receivership was made by William M. Stevenson, secretary of the company.

THE CONSUMERS' VEGETABLE GLUE Co., a Delaware corporation, has filed notice of organization to operate in Indiana for the manufacture of glues, pastes, etc. F. B. Shields, Indianapolis, represents the company.

THE LAKE CHAMPLAIN PULP & PAPER Co., Plattsburg, N. Y., has filed notice of dissolution under state laws.

THE MITCHELL LIME Co., Mitchell, Ind., has filed notice of change of name to the Lehigh Lime Co.

THE THOMPSON-CASE OIL & RUBBER Co., Chattanooga, Tenn., has filed notice of increase in capital from \$15,000 to \$50,000. The company formerly was known as the Thompson-Case Rubber Co.

THE UNITED STATES CHINA Co., Chester-ton, Ind., manufacturer of chinaware, has filed notice of increase in capital from \$200,000 to \$875,000, at the same time changing its name to the American China Products Co.

THE SOUTHERN GYPSUM Co., North Holston, Va., manufacturer of gypsum products, has filed notice of increase in capital from \$500,000 to \$750,000.

THE CORTLAND TIRE & RUBBER Co., Cortland St., Belleville, N. J., has filed notice of dissolution under state laws.

New Companies

THE AMERICAN OXYGEN CORP., Boston, Mass., has been incorporated with a capital of \$100,000, to manufacture commercial oxygen and affiliated products. Charles E. Donlan is president; Clinton B. Sherwood, Swampscott, Mass., is treasurer.

THE DRY PAINT CORP., Detroit, Mich., has been incorporated with a capital of \$10,000, to manufacture paints, varnishes, etc. The incorporators are George A. Smith, Lowry C. M. Conley and Andrew B. Couchman, 1529 Glendale St.

THE OIL REDUCTION Co., Hudson, N. Y., has been incorporated with a capital of \$300,000 under Delaware laws, to manufacture refined oil products. The incorporators are Riland S. Eagles, Hudson; Eugene F. Dumennil and Walter S. Griffin. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington, Del.

THE FERMANOS CHEMICAL Co., Brooklyn, N. Y., has been incorporated with a capital of \$10,000, to manufacture chemicals and chemical byproducts. The incorporators are B. Barbera and F. Maggio. The company is represented by Giaccone & Richard, 154 Wilson Ave., Brooklyn.

THE CHATTANOOGA MIRROR PLATE Co., Chattanooga, Tenn., has been incorporated with a capital of \$20,000, to manufacture mirrors and other glass products. The incorporators are F. R. Hymes and Spaulding Hoffman, Chattanooga.

THE ILLINOIS-ARKANSAS OIL Co., Havana, Ill., has been incorporated with a capital of \$45,000, to manufacture petroleum products. The incorporators are E. J. List, H. A. Starkweather and Carl H. Hillemeier, 121 South Orange St., Havana.

THE PEP GLAND Co., Jersey City, N. J., has been organized to manufacture chemicals and chemical byproducts. The company is headed by J. R. and B. F. Cortese, and P. G. Flint, 5 Montgomery St.

THE JOHN E. DANIELS LEATHER Co., Boston, Mass., has been incorporated with a capital of \$20,000, to manufacture leather products. John E. Daniels, 69 Kenwood St., Brookline, Mass., is president and treasurer.

THE ZOCH-BARNES PETROLEUM CORP., Wilmington, Del., has been incorporated with a capital of \$5,000,000, to manufacture refined oil products. The company is

represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE HOBOKEN RUBBER Co., 54 Fourteenth St., Hoboken, N. J., has filed notice of organization to manufacture rubber products. The company is headed by Frank J. Doran, 1221 Washington St.

THE ARNOLD CHEMICAL Co., Boston, Mass., has filed notice of organization to manufacture chemical products. The company is headed by A. S. Brodie, 120 Milk St.

THE ROCHELL PRODUCTS Co., Philadelphia, Pa., has been incorporated under Delaware laws with a capital of \$100,000, to manufacture chemicals and chemical byproducts. The incorporators are Harry Rochell, William J. Dougherty and Martin J. Lyons. The company is represented by Philip L. Garrett, Equitable Building, Wilmington, Del.

THE INTERSTATE PETROLEUM PRODUCTS Co., Fort Wayne, Ind., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are J. F. Blippus, Frank Martin and Milton Matter, Fort Wayne.

THE ROXBURY STEEL CASTING Co., Boston, Mass., has been incorporated with a capital of \$50,000, to manufacture steel and other metal castings. Isaac E. Sexton is president; Perley C. Rogers, Quincy, Mass., is treasurer.

THE PHOENIX BELTING & OIL Co., 198 Pacific St., Newark, N. J., has been incorporated with a capital of \$100,000, to manufacture oils, greases, leather belting, etc. The incorporators are Benjamin, Matthew M., and Leon Gallop, address noted.

THE SANITARY BOTTLE MFG. Co., West Pittston, Pa., has been incorporated with a capital of \$200,000 under Delaware laws, to manufacture bottles and other glass containers. The incorporators are L. O. Culver, West Pittston; George W. Culver, Forty-Fort, Pa.; and D. O. Coughlin, Luzerne, Pa. The company is represented by the Capital Trust Co., Dover, Del.

THE SETH LEE FIREBRICK Co., Boston, Mass., has been incorporated with a capital of \$300,000, to manufacture firebrick and other refractory products. Thomas W. Pelham is president; Martin J. Lee, vice-president; and Seth Lee, 100 Carver St., Newton Highlands, Mass., treasurer.

THE ABBOTT-CADE ENAMELING Co., Dallas, Tex., has been incorporated with a capital of \$10,000, to manufacture enameled products. The incorporators are N. F. Wertheimer, H. L. Bromberg and C. S. Reynolds, Dallas.

THE RIVERSIDE BRICK & TILE Co., Knoxville, Tenn., has been incorporated with a capital of \$40,000, to manufacture brick, tile and other burned clay products. The incorporators are R. P. Black, J. W. Dooley and B. C. Ogle, Knoxville.

THE WAUKEGAN FOUNDRY Co., Waukegan, Ill., has been incorporated with a capital of \$60,000, to manufacture iron, steel and other metal castings. The incorporators are Andrew K. Barr, Elmer T. Kidmore and Elmer Olavey. The company is represented by Benjamin Farmalee, Waukegan.

THE EL DORADO REFINING Co., New York, N. Y., has been incorporated with a capital of \$500,000 under Delaware laws, to manufacture refined oil products, with plant in the vicinity of Texarkana, Tex. The incorporators are G. W. and L. A. Merrill, Texarkana; and L. F. Severson, Tulsa, Okla. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE KRANISH CHEMICAL Co., Brooklyn, N. Y., has been incorporated with a capital of \$20,000, to manufacture chemicals and chemical byproducts. The incorporators are A. and H. Kranish, and J. G. Turnbull, 27 Cedar St., New York.

THE TRAVERTINE PRODUCTS CORP., Livingston, Mont., has been incorporated with a capital of \$500,000, to manufacture cement, lime and kindred products. The incorporators are C. T. Sackett and L. R. Nye, Livingston.

THE INDUSTRIAL SUPPLY Co., New Haven, Conn., has been incorporated with a capital of \$10,000, to manufacture chemicals, polishing materials, etc. The incorporators are James F. and M. Toole, 144 Townsend St., New Haven.

THE KAOLIN PRODUCTS CORP., Los Angeles, Cal., has been incorporated with a capital of \$500,000, to produce kaolin, clays and kindred products. The incorporators are G. A. Elcheberger, M. L. Gilmore and H. P. Goodwin, 232 Title Insurance Bldg., Los Angeles.

THE VANO PRODUCTS Co., New York, N.

Y., has been incorporated with a capital of \$10,000, to manufacture chemical compounds and affiliated products. The incorporators are F. A. Nelson, I. Price and J. Weiner. The company is represented by Price Bros., 261 Broadway.

THE MOUNTAIN CITY CHEMICAL Co., Fairmont, W. Va., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts. The incorporators are R. P. and C. E. Hutchinson, and J. V. Abbott, Fairmont.

THE OLYMPIC OIL CORP., Tralee, W. Va., has been incorporated with a capital of \$100,000, to manufacture petroleum products. The incorporators are J. C. Sullivan and J. F. Korner, Tralee.

THE INDIANAPOLIS MOLDED RUBBER PRODUCTS Co., Indianapolis, Ind., has been incorporated with a capital of \$100,000, to manufacture rubber products and composition specialties. The incorporators are F. L. Tompkins and T. S. Stewart, Indianapolis.

THE OREGON CHARCOAL IRON Co., Portland, Ore., has been incorporated with a capital of \$500,000, to operate a smelting plant. The company is headed by J. H. Kelly, 1524 Yeon Bldg., Portland.

THE HAMMOND GREASE & OIL Co., Hammond, Ind., has been incorporated with a capital of \$15,000, to manufacture greases, lubricating oils, etc. The incorporators are M. M. Dermody, O. B. Loyd and W. H. Breckenridge, Hammond. The last two noted incorporators have also organized the Lloyd-Breckenridge Grease Co., Hammond, to manufacture greases, soaps, oils, etc.

THE MAXWELL PAINT Co., Philadelphia, Pa., is being organized by H. C. Middleton, Roy M. Boyd and William A. Stuetz, to manufacture paints, varnish, sizing and kindred products. J. Claude Bedford, Liberty Bldg., represents the company. Application for a state charter will be made on Oct. 3.

THE ALABAMA LIME Co., Chattanooga, Tenn., has been incorporated with a capital of \$10,000, to manufacture lime products. The incorporators are A. C. Noone, Horace Hamby and C. N. Miles, Chattanooga.

Industrial Notes

SIECK & DRUCKER, Inc., mechanical and chemical engineer, Chicago, Ill., announces it has associated with itself Herbert Sieck, formerly in charge of operations of the Chicago properties of the American Cocoa-nut Butter Co.

THOS. FIRTH & SONS, LTD., Sheffield, England, has terminated its agency arrangement for the sale of sheet steel heretofore existing between it and Wheelock Lovejoy & Co., of New York and Cambridge, and has appointed Horace G. Hides as general sales manager for the United States. This company and the Firth-Sterling Steel Co., an associate company of New York, have opened a joint office in Hartford, Conn., where Mr. Hides will have his headquarters for the former company and Henry I. Moore will represent the latter company. The stock of the Firth Sheffield sheets will be carried in the warehouse of the Firth-Sterling Steel Co., New York City.

GEORGE C. D. LENTH has been appointed secretary of the Clay Products Association, with offices in Chicago, to succeed the late George H. Tefft. Mr. Lenth is a graduate of the Massachusetts Institute of Technology and has for some time been chief engineer of sewers of the City of Chicago. He will follow out one of the chief lines of endeavor of this society at the present time—namely, the promotion of vitrified and salt glazed sanitary sewer pipe to resist chemical action of sewage.

STUART CROASDALE & Co. announce the removal of Pittsburgh offices from the Magee Bldg. to 946 Union Arcade Bldg.

THE LINK-BELT Co., Chicago, announces a practically uniform reduction of 10 per cent on malleable iron and steel (SS Class) chains, sprockets, buckets and other products, effective at once.

THE GENERAL ALLOYS Co., New York and Chicago, announces a new heat-resisting alloy, under the trade name of X-ite. It is the fourth standard material to be sold by this company under the Q alloy trade name.

THE TEXAS GULF SULPHUR Co. announces the removal of its offices to larger quarters in the Liggett Bldg., at 41 East 42nd St., New York.

E. I. DU PONT DE NEMOURS & Co., Wilmington, Del., announce that Cesare Protto has been appointed assistant director of the sales division of the dyestuffs department in place of E. V. Patterson, who has re-

signed. Robert S. Lunt has been appointed manager of the Boston office of the dye-stuffs sales division, with Charles H. Scott as assistant manager.

DWIGHT P. ROBINSON Co., INC., New York, has published a chart showing the range of index numbers of wholesale prices by groups of commodities by months, 1913-1921.

ROGERS, BROWN & Co., Cincinnati, Ohio, have been appointed sole agents in the United States for the sale of Virgin aluminum, of various grades, produced by the Norsk Aluminum Co. of Christiania, Norway. Stocks of aluminum will be carried at the New York City and Cleveland, Ohio, offices of the company.

THE CUTLER-HAMMER MFG. Co., Milwaukee, Wis., has moved its Cincinnati office from the Gwynne Bldg. to the Dixie Terminal Bldg. A. R. Maujer, formerly of the sales-engineering force of the Pittsburgh office, is now in charge of the Cincinnati office.

THE CHICAGO FLEXIBLE SHAFT Co. has placed Ralph C. Schwarz in charge of the northwestern New York territory for the distribution and sale of Stewart industrial furnaces and appliances. Mr. Schwarz's address will be 921 Granite Bldg., Rochester, N. Y.

FORD, BACON & DAVIS, New York, have opened an office in Philadelphia at 1421 Chestnut St. This engineering firm has the following departments, which are adapted to meet present economic conditions: Engineering, report, valuation, accounting, construction, management and financing.

THE SOCIÉTÉ ANONYME DES USINES GIULINI, Basel, Switzerland, manufacturer of Virgin aluminum ingots, notched bars, bars, plates and sheets, has appointed C. W. Leavitt & Co. sole selling agents for the United States and Canada.

THE M. H. DETRICK Co., Chicago, maker of Detrick arches and Detrick-Hagan steam jet ash conveyors, announces the appointment of H. W. Thompson, 503 Mining Exchange Bldg., Denver, Col., as sales representative in that territory.

THE W. A. JONES FOUNDRY & MACHINE Co., Chicago, has elected T. A. Jones president, to take the place of William A. Jones, deceased. Mr. Jones has been for many years associated with the company as secretary and treasurer and is largely responsible for its firm position. Other officers elected are: W. G. Jones, vice-president and treasurer; J. A. Sizer, secretary; G. W. Page, assistant secretary. The general policy of the company is in no way altered by these changes and W. G. Jones continues as general manager in addition to his new position as vice-president and treasurer. This company also announces the appointment of Robert B. Moir as manager of its New York branch.

THE RADIUM LUMINOUS MATERIAL CORP. at a recent meeting of the board of directors decided to change its name to the United States Radium Corp. The control and management of the corporation remain unchanged.

BANKS & CRAIG, engineers and chemists, have moved to new quarters at 51 East 42nd St., New York City.

THE TECHNICAL CREDIT ASSOCIATION, 2 Rector St., New York City, announces that it is organized to make investigations including: Geological, chemical, mining, metallurgical, electrical, with expert sampling and accounting, efficiency engineering and appraisal of raw material resources and supplies, equipment, processes and management of properties and operations, for the purpose of sustaining or establishing credit.

HUNGERFORD & TERRY, Philadelphia, Pa., have appointed the Hurricane Engineering Co., 53 State St., Boston, Mass., selling agents for its apparatus in the New England territory. The managing director of the Hurricane Engineering Co. is E. L. Smith, for years the New England representative of the Philadelphia Drying Machine Co. The entire line of water filters, water softeners, iron removal plants, hypochlorite feeds and other feeding devices manufactured by Hungerford & Terry, Inc., will be handled by the Hurricane Engineering Co.

F. J. RYAN & Co., Philadelphia, Pa., announce the establishment of three additional agencies. They are as follows: Detroit, under the direction of David P. Harr, 423 Depot St., Latrobe, Pa., who will also cover the Cleveland and Toledo districts; Chicago, under the direction of the Singer Kennedy Construction Co., 39 W. Adams St., Chicago, Ill., who will cover the Middle West; L. H. Chamberlain, 72 New Montgomery Ave., San Francisco, Cal., will cover the Pacific Coast. F. J. Ryan & Co. have

recently moved their general offices and sales from the Franklin Trust Bldg. to larger quarters in the Wesley Bldg., 17th St. and the Parkway, Philadelphia, Pa. The removal is also announced of the engineering departments to Lancaster, where they will be established in the headquarters of the Lancaster Iron Works, with which F. J. Ryan & Co. became associated in the early part of the present year.

J. SCHANZENBACH & Co. has been organized by former department heads of the old house of Laidlaw-Kelly & Co., and is organized to engage in handling chemicals, oils, waxes, dyestuffs, etc. The company's office is 74 Cortlandt St., New York City.

L. R. CHRISTIE Co., engineer, Pittsburgh, Pa., specializing in the design of drying machinery, has granted the Duff Patents Co. of Pittsburgh sole license and rights to manufacture driers of the Christie patents and design.

New Publications

BOOKS

THE MINERAL INDUSTRY OF THE BRITISH EMPIRE AND FOREIGN COUNTRIES. Statistical Summary (Production, Imports and Exports), 1913-1920. 104 pages. London: Printed by H. M. Stationary Office, 1921. Price 3s. 0d. net.

This title sufficiently describes the scope of the book which is planned to be the first of series of annual volumes. It consists of tabular matter exclusively, with no textual comment, but covers the war years fully, 1919 completely, and 1920 in part. Particularly valuable will be the figures for the mineral production of the enemy countries. Not only are minerals, such as chromite, asbestos and gypsum, included, but metals, such as copper, ferromanganese, silver, etc.

WATER POWERS OF GEORGIA, THIRD REPORT. By B. M. Hall and M. R. Hall. Pp. 316, illustrated. Atlanta, Ga.: Geological Survey of Georgia, 1921.

USEFUL INFORMATION FOR COTTON MANUFACTURERS, VOL. IV, AIR CONDITIONING, second edition. Compiled and issued by Stuart W. Cramer, Charlotte, N. C.

A study of air-conditioning problems as related to textile mills, with a description of the Cramer system of air conditioning.

CONCENTRATION BY FLOTATION. Compiled and edited by T. A. Rickard. Pp. 692, illustrated. New York: John Wiley & Sons, Inc., 1921. Price, \$7.

Forty articles dealing with all phases of the flotation process which appeared in the *Mining and Scientific Press* during the years 1915 to 1920 have been brought together in book form by the editor. This compilation will thus serve as a convenient compendium of the principal literature on the technology of flotation.

COLORIMETRIC ANALYSIS. By F. D. Snell. Pp. 150; illustrated. New York: D. Van Nostrand Co., 1921. Price, \$2.

This book is an attempt to combine in one volume for ready reference all the colorimetric tests which experience has shown to be at all practical. These have been grouped under the heads: Iron; copper; carbon in steel; lead, bismuth and arsenic; aluminum and chromium; nickel, cobalt, manganese and zinc; potassium and magnesium; gold; titanium, vanadium and tungsten; fluorine, chlorine and perchlorates; nitric and nitrous acids, ammonia; phosphorus, silica and boron; oxygen and hydrogen peroxide; sulphur, hydrogen sulphide and selenious acid; salicylic acid and cyanides; water, oils and dyes. Chapters on conditions of use of colorimetric methods, colorimetric apparatus and its use, and nephelometry are also included.

ELEMENTARY QUANTITATIVE ANALYSIS OF THE METALS AND ACID RADICALS. By Frederick G. Reeve, E.E., acting head of the department of physics and chemistry at the East Side High School, Newark, N. J. Pp. 143. New York: D. Van Nostrand, 1921. Price, \$1.50.

An elementary laboratory manual.

THE ENGINEERING INDEX, 1920. Pp. 586. New York: The American Society of Mechanical Engineers, 1921. Price, \$6.

Nearly 14,000 items referring to articles in 700 engineering and allied technical publications will be found in this index. The alphabetical arrangement which proved to be so convenient and satisfactory in the 1919 volume has been retained. Each item contains the exact title of the article indexed; the author's name, if given; the name of the publication; the volume, number and date; the page numbers and number of figures. It also includes a brief note summarizing the article indexed.

Manufacturers' Catalogs

ALLIS-CHALMERS MFG. Co., Milwaukee, Wis., calls attention to bulletin 1118, descriptive of its new line of continuous rated polyphase induction motors, covering the type "AR" squirrel cage line, and type "R" potential starter; Leaflet 1459 entitled "Fullers Earth," which relates to rotary kilns for reclaiming this product, and Bulletin 1106 A, on "Type 'E' Direct-Current Motors and Generators."

W. S. ROCKWELL Co., New York, has issued a very interesting and instructive pamphlet on Furnace Design. It contains 13 pages of outline drawings showing the essential parts of over 250 different styles of heating and heat-treating and melting furnaces and muffles, both manual and automatic, intermittent and continuous, regenerative and otherwise. The pamphlet closes with a drawing showing about three dozen arrangements of furnace chambers and working openings to which nearly all of the types illustrated could be adopted. This company also announces that a general misunderstanding of principles governing the selection of fuel and equipment for industrial heating operations has led it to issue a pamphlet which contains a series of papers relating to the selection and use of fuels and equipment for industrial heating operations.

THE PENNSYLVANIA TANK LINE, Sharon, Pa., calls attention to its attractive catalog entitled "The Tank Car." All of the latest special rulings, traffic regulations and repair charges as fixed by the American Railway Association have been included in this catalog. It also shows in detail the numerous accounting forms, technical engineering charts and half-tone reproductions of this company's construction.

THE ANTI-HYDRO WATERPROOFING Co., Newark, N. J., has issued a leaflet on "Anti-Hydro," which hardens and waterproofs concrete.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting at Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

INDUSTRIAL COST ASSOCIATION will hold its second national conference at Pittsburgh, Pa., Nov. 2-4, with headquarters at the William Penn Hotel.

INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA will hold its annual convention at the Waldorf-Astoria, New York, Nov. 1-5.

NATIONAL SAFETY COUNCIL is holding its tenth annual conference at the State House, Boston, Mass., Sept. 26 to 30.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (In charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

Number 14

Conferences and Publicity On Unemployment

HOOPER'S bent for organization was in evidence when the unemployment conference gathered, setting a mark which the meeting on disarmament will find difficulty in hitting. The invited conferees found the mechanical details had been well arranged; adequate rooms, stenographic and clerical service were in waiting. Not only that, but a tentative plan of organization and procedure had been prepared, a plan which was under discussion by a special committee within an hour after President HARDING had delivered his opening address. By 3 o'clock the committee's report had been considered, the main body had resolved itself into smaller units and each was working on some phase of the unemployment situation, using as raw material a mass of facts, records and statistics gathered during the preceding weeks by qualified investigators.

With such a flying start, an emergency program was reported on October 1, five days ahead of the tentative schedule, and final meeting of the general conference will occur on October 10, when a permanent program will be considered.

New and brilliant ideas can scarcely be expected from this meeting—no panacea short of a millennium will cure the various ills afflicting the nations of this earth. But even the emergency program should result in vigorous and widespread propaganda, calling on every one to aid according to his circumstances and ability. Construction by governments and municipalities can be broadened by each establishment and even each property owner going ahead with needed repairs and renewals. A tremendous amount of unemployment will disappear when adequate steps to relieve the housing shortage are taken. Furthermore, if manufacturers, all manner of middlemen and retailers would think more on production and distribution with the greatest expedition and minimum waste rather than with the greatest profit, reasonable prices to the ultimate consumer would again obtain, and the buyers' strike vanish into thin air.

Exorcising profiteers with the fair name of patriotism is a waste of breath. Adequate publicity on unemployment, however, will stress the fact, and perhaps blast its way into consciousness, that "bare shelves" in Germany cannot be filled by us as long as marks are not worth a cent; that times will therefore be good in the United States only if domestic trade is thriving; that "unsatisfied consumer demand" in America has less and less chance of becoming satisfied as long as unemployment and low prices on raw materials, coupled with high retail prices, combine to prevent purchases by the men and women who must work for their living. If foreigners cannot buy, we must depend on our neighbors. But if the farmer gets next to nothing for his hides, and the longshoreman has no work, how can either of them buy \$10 shoes?

Anent Peace With Germany

ON THE DAY the treaty of peace was signed between the United States and Germany they had a great meeting in Berlin. Thirty thousand persons participated, and their leaders were Prince EITEL FRITZ and General LUDENDORFF. The old regiments paraded and fair daughters of the Empire strewed flowers before them. The bands played "Die Wacht am Rhein." "Undefeated in the Field" was the slogan that floated over the stadium. "With proud gratitude," wrote the old Kaiser from Holland, "I think today of my brave comrades, never vanquished in the field," etc. We suppose he referred to those that did not run away as he did. What he said about the beacon for victorious illumination in the dark future was not very important, because whatever he says is not important. But the threat of his presence as a symbol is not to be despised. Count VON WALDERSEE said, "There will come again a day when we will stand together for Kaiser and for Fatherland. Hatred will stand guard in Germany. We must train our children to use the rifle and the sword." And he urged them to prepare for revenge, revenge for their present impotence.

Well, what is to be done about it? It behooves us to keep our tempers and think before we act. Fulminations at a mass meeting are not final and binding. We might hear a lot of dicta that we should hate to publish as public opinion by listening to soap-box orators, almost any evening, on the streets of New York or, for that matter, published in current journals.

We have always felt that it was a great error not to lick the Germans a little harder than we did—until they knew that they were licked. With two weeks more of chasing they would have been Kamarading it all over Europe wherever they could make themselves heard. They might have brought influence to bear on these orators of the other day to be more modest in their expressions. If we are to trade with Germany as a friendly nation, we want to know it. If we are to trade with a race of people who are resolved to destroy us for their own infamous aims of the past, it is well that we should know that too.

It is not fair to indict a whole people for what their rulers do. But if they persevere in selecting rulers who lead them astray they must take the consequences of going astray. Our business is to wait and observe. If they cannot govern themselves and if they establish a war-lord king again, then the less we have to do with them in the way of commitments and obligations the better it will be for us. It would be a great mistake to tie ourselves up with German industries once more so that we cannot get along without them. The wise course will be to keep other markets open and reasonably active, no matter what they offer and to make ourselves as self-sufficient and independent as humanly possible.

When Is a Research A Mere Inquiry?

ARE we not, many of us, often guilty of loose talking when we talk about research?—guilty of calling researches things which are often nothing more than systematic tests? A real researcher is as jealous of his proud calling as an engineer, and, like the latter, must rebel at times against the lack of precision which associates several different branches of human endeavor with his calling.

These thoughts were called to mind at a session on Research at the recent meeting of the American Society for Steel Treating, addressed by no less personages than E. P. HYDE, Director of Research at Nela Park; COMFORT A. ADAMS and H. E. HOWE, of the National Research Council; A. E. WHITE, Director of Engineering Research, University of Michigan; and GEORGE K. BURGESS, of the Bureau of Standards. Dr. HYDE opened the way to a blanket discussion by presenting and elaborating the following interesting outline:

RESEARCH

(A) SCIENTIFIC

(a) *Pure Scientific Research*

- (1) Frontier research. (Best performed at universities and privately endowed laboratories.)
- (2) Intensive and co-operative research. (Best performed by governmental, endowed or corporation laboratories.)

(b) *Applied Scientific Research*

- (3) Industrial research. (Best performed in corporation and private laboratories.)

(B) ENGINEERING

- (4) Engineering research. (Best performed by the government, corporations, technical school and private laboratories.)
- (5) Engineering practice. (Best performed in corporation and private consulting laboratories.)

These five classes cover a wide range. Even though dictionary definitions may be discovered that show "research" to include them all, we protest that it is too much. Item No. 1 doubtless is RESEARCH, resulting in the discovery of a new and unknown fact. No. 2 takes this fact and proceeds to an EXAMINATION of it from all angles. No. 3 devises APPLICATION of the new truth to human comfort; No. 4 is often nothing more than TESTING of materials, and the last is usually mere EXPERIMENTATION.

Research is often, and with reason, likened to a *voyage of discovery*, out into the unknown country. Land once discovered, then comes the task of *map making*, followed by necessary *road building*. Next comes an era when the *fields are cultivated* or other natural resources exploited, and lastly, when the land has been well settled, comes the necessity for *crop rotation* and fertilization. These phases in the development of a new land roughly correspond to the five classes of "research" listed by Dr. HYDE; and we submit that it is a far cry from the trackless forest to the truck garden.

Or, drawing another rough parallel between the kind of men who do the investigative work and the men who develop a country, first we have the EXPLORERS who push out into the jungle; then come the PIONEERS entering the wilds. After them follow CAPITALISTS building up industries demanding the services of ARTISANS, and finally are acquired PRODUCTION ENGINEERS! Even allowing for a certain freedom in this characterization, surely there are profound differences in the mental and spiritual equipment of these five classes of men.

So, we repeat, let us be a little more careful in our use of terms. We instinctively place the title "sales

metallurgist" in the Index Expurgatorius. Let us be as circumspect in calling a research a few experiments yielding a few approximations of certain physical properties of something or other. The work may unquestionably be worth while; but it is not research, nor is it done by a researcher.

Student Chapters

For the A.I.C.E.

ONE of the questions awaiting final decision by the American Institute of Chemical Engineers at its coming meeting in Baltimore is the proposal to establish student chapters of the Institute. At Detroit, last June, the matter was reported favorably to the council, but the amendment to the constitution, in its final form, is yet to be approved. In taking this step the Institute is following the example set by several of the other engineering societies. The American Society of Mechanical Engineers now has fifty-eight student branches representing institutions located in thirty-one different states. The American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Institute of Electrical Engineers and the American Ceramic Society have provided for affiliated student societies, and it would appear that these branches have been mutually beneficial—both to the students themselves and to the members of the parent societies.

Probably the most obvious advantages are to the student. Contact with the professional organization stimulates the student's interest in his chosen field. The privilege of attending the society meetings brings with it the opportunity for social intercourse with the older members and the benefit of their advice and council. The meetings of the student chapters also develop the student's ability to present technical papers before an audience—and it is evident that many of the more seasoned engineers show the need for such practice. And finally, in the case of some of the societies, the student is given the expectation of some day becoming eligible to junior, associate or active membership.

The mother organization, too, is forwarding its own interests by this early introduction of the engineering student to the purposes and functions of the society. The men in the colleges today are the men in the industries tomorrow, and it is worth while for the societies to keep in touch with them and to follow their progress. Furthermore, by furnishing speakers and councilors to the student chapters the society is carrying on a great educational work for the profession which it represents. The colleges and universities, in turn, are benefited by the *esprit de corps* fostered among the students. The better realization of future responsibilities makes for a more serious purpose on the part of the student, and this should be reflected in the scholastic standing of the institution.

All of these worth-while purposes can be accomplished in the field of chemical engineering. The indefinite status of the chemical engineer in some institutions and the continual jostling back and forth between the chemists and the engineers, with recognition by neither, has resulted in an unhappy situation for the student in chemical engineering. If, however, he can become affiliated with a professional organization of the character and recognized standing of the Institute and if, for his guidance, he can look to its members and their accomplishments in the chemical industry, his status will have been improved materially.

The Dye Industry And Modern Warfare

THERE is a book lately published by Dutton & Co. which we propose to review at length some day when time is less pressing, called "The Manhood of Humanity, or Human Engineering," by Count ALFRED KORZYBSKI. It brings out the fact that we have passed the childhood of Humanity, and are now grown up. We may like our old toys and our childish ways, but we know better. For the first time in literature as we know it a definite answer is given to the question, "What is man?" The book is a work of amazing enlightenment.

The opening of the Chemical Exposition brought the idea to mind. We are grown up. Senator LENROOT and General FRIES both called attention to the immense significance of chemical warfare. "We have entered into a treaty of peace with Germany," said the Senator, "and her battleships are sunk and her army disbanded. But her greatest stronghold remains. Her great arsenals of chemical warfare are unimpaired." It is fair to say that Germany today is the strongest military power on earth because *warfare has changed*. We may not like it, but that does not alter the fact. We remember the flare and the dash and the grand appearance of cavalry troops, but of what value are they really? A battalion of well-trained chemical warfare troops can put a whole division of cavalry out of business. General FRIES spoke of the sinking of warships by bombs dropped from the air, and called attention to the fact that this was done without the aid of smoke. If the warship that was sunk had been manned by an enemy crew a dose of smoke would have put all their air defenses out of business, while explosive bombing would have sunk her. Warfare has changed, both on sea and on land; and warfare in the air has been added. General FRIES also declared that without an active and progressive chemical industry engaged in intensive organic synthesis over a broad field, of which the dye industry is but one branch, a nation is without military defense.

Senator LENROOT said we may agree on limitations of armament and war materials as much as we please, but we must not agree to any limitation of scientific activity. We must not agree to prevent our scientists from working for national defense, and he earnestly hoped that the country will recognize the need of this.

General FRIES reminded the audience that not one new chemical was used in the late war. Everything used was known before. Making mustard gas, for instance, was a slow process until Sir WILLIAM POPE invented the new and rapid one which was eventually put to use. But even by the slow process the Germans *had the facilities* in their dye-works, and it is reported now that a new indigo technique lends itself by a slight transformation to the production of mustard gas. He joined Senator LENROOT in the willingness to enter into any agreement as to limitation of defenses and armament, but said that the last thing on earth to do is to agree not to use chemical warfare on an attacking enemy.

There is a powerful lot of thinking to be done these days. And in the face of the fact that the old order is not only changing but has changed already, we lose all safety in conservatism. We must seek our welfare in understanding and in wisdom. And we must not forget that chemistry can do.

"Normalcy" and Extrapolation

WE HAVE HEARD so much lately about "returning to normalcy" that the word has become somewhat nauseous to quite a few. Sometimes we have to deal with unpleasant expressions just as we must deal frequently with unpleasant things. Undoubtedly the idea is all right, and if the thing still has to be talked about, it is because the operation has not been completed.

Now the word "normal" may be used in connection with various things, such as a state of mind, a rate of doing work and a volume of business. If we think of "normal" in connection with a state of mind, we mean simply a sensible, reasonable, rational state of mind. There is no room for argument there. All of us should be that way. Usually or frequently we are not, so "normal" in that case scarcely means "natural" and it is not even interchangeable with "average."

Dismissing the concept of "normalcy" in connection with a state of mind as being something we cannot disagree upon, one observes the desire to judge business affairs by reference to "normal," and it is plain that very often this requires extrapolation. When a period of time has passed it is not difficult to decide what was normal during that period, but we are always at the center of time. The past is behind us, the future before us. Hence we must extrapolate.

The problem is really to determine when to extrapolate and when not to extrapolate. We see many references to "pre-war prices." That is far from extrapolation, since such statements refer to a period ended seven years ago. When we consider quantities of business, on the other hand, nearly everyone is disposed to extrapolate. We expect expansion and increase. Normal today is not the average of past years, but the average of past years plus future years.

Now in extrapolation we can easily make serious mistakes. For instance, the production of coal was 219,976,267 tons in 1898 and 357,356,416 tons in 1903. That represented an annual rate of increase of 10.2 per cent, equal to a doubling in a trifle over seven years. If at the end of 1903 one had extrapolated to 1922 he would have found 2,259,000,000 tons as the proper production for next year. This year's production is expected to be about 425,000,000 tons. To follow the rule, next year's production should be five times as much, not to speak of making up for lost time. This is fanciful, and no one tries it, but substantially that sort of thing really has been argued as to pig iron. Men have taken the previous rate of increase, carried it forward, and computed the number of tons by which the world was deficient, insisting that the world would probably try to make it up, if not to regain the former pace.

Between returning to pre-war conditions and conditions indicated by extrapolation there is a very wide gap, and yet the proper applications of "normalcy" hit points all the way from the one extreme to the other. We want to be normally useful. We should think not of quantities of coal, but of useful results. The total quantity of coal produced has been increasing, but the quantity per unit of work, electric light thrown on the machine tool, or locomotive drawbar pull, has been decreasing. We should think less of the quantities that go into the statistics and more of the useful results attained, measuring success not by quantities of money or materials or hours employed but by useful work accomplished.

Readers' Views and Comments

Boiler Feed Water Purification

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the article on "Boiler Feed Water Purification," which appeared in your issue of July 6, the author makes a number of interesting points whose correctness will be conceded by all specialists in industrial water purification. In his zeal, however, he makes several statements which probably would never have seen the light of publication had he been writing from a strictly impartial standpoint.

In a former capacity as chemist for one of the larger manufacturers of zeolite water softeners I have analyzed at various times the effluent from many zeolite water softeners; Permutit, Refinite, Borromite and De-Calco were all included. These analyses without exception have shown that Mr. Applebaum overstates his case very, very badly when he writes as follows: "Slight amounts of hardness in the effluent of some zeolite softeners have been noticed in some cases; but this can mean only that the particular zeolite softeners examined were improperly designed and that the volume of a proper grade of zeolite used was not in sufficient excess so that the softener was seriously overloaded."

... If the size of the zeolite softener is correctly selected to take care of the required volume of water containing a known hardness, the effluent of the softener is always of zero hardness."

It is obviously impossible that these statements could be correct, except by taking the meaning given by the zeolite manufacturers themselves to the term "water of zero hardness." As I understand it that meaning is: Any water which, titrated against standard soap solution, produces a permanent lather with an amount of soap solution representing 1.4 grains per gal. or less of hardness, expressed in terms of CaCO_3 . The very law which makes zeolite water softening a commercial possibility—the law of mass action (which is but a phase of the law of ion concentration)—renders it impossible to remove entirely all Ca and Mg from natural supplies of water. On account of this law, whereby the excess of the sodium in the zeolite forces an exchange for the Ca and Mg in the water, waters having a high sodium content cannot be successfully treated, for the exchange ceases where the point of equilibrium is reached between the sodium in the zeolite and that in the water. In waters of low sodium content, the exchange can progress much nearer completion, but the point of equilibrium is nevertheless reached before the Ca and Mg have been entirely eliminated from the water. When this point of equilibrium is reached, were we to add a slight—a *very* slight—amount of some sodium salt to the water, the equilibrium being disturbed, a reverse reaction would take place, until the equilibrium was restored.

In an article which appeared several months ago¹ the writer quoted an analysis of a representative zeolite-treated water, the hardness of which expressed in terms of CaCO_3 was 0.50 grain per gal. (This, incidentally, is as nearly free from Ca and Mg as has

been any sample of zeolite-treated water which I have analyzed.) This is the analysis to which Mr. Applebaum refers in the paragraph quoted above. It is possible that he may have been misled by a typographical error, corrected in a later issue, whereby the CaCO_3 equivalent hardness of this zeolite-treated water was given as 6.50 grains per gal., but an examination of either the context or of the analysis itself should have corrected any such false impression, for the analysis showed CaCO_3 0.25 grain per gal. and MgCO_3 0.21 grain per gal.

He also makes the following assertion: "It is falsely claimed that zeolite-softened water increases the tendency of boilers to foam, on the consideration that the sodium salts have a heavier molecular weight by about 5 per cent than the corresponding calcium or magnesium salts."

This appears to be a misinterpretation of point 1 in the discussion of the disadvantages of the zeolite system of water purification in the article mentioned above.² The unquestioned tendency of zeolite-treated waters to foam should not be attributed to a difference in molecular weight. The cause for this increased tendency is the increased amount of sodium salts in the water, the Ca and Mg being replaced by sodium, and sodium salts being notorious offenders in causing foaming, a property almost entirely absent from Ca and Mg salts.

Furthermore, his chemical arithmetic is not accurate. In the average natural water, on account of the fact that the CaCO_3 is held in solution by half-bound CO_2 , a quasi-bicarbonate, 1.00 grain per gal. of CaCO_3 is not replaced by 1.06 grains per gal. of Na_2CO_3 , but rather by 1.68 grains per gal. of NaHCO_3 ; and 0.84 grain per gal. of MgCO_3 is replaced by 1.68 grains per gal. NaHCO_3 ; exactly double the amount. Take, for example, a water whose analysis showed 10.00 grains per gal. CaCO_3 , 8.40 grains per gal. MgCO_3 and 2.60 grains per gal. of sodium salts—total, 20.00 grains per gal. Ignoring the small amount of Ca and Mg salts which would remain unchanged, the zeolite-treated water would show 33.60 grains per gal. NaHCO_3 , 2.60 grains per gal. of other sodium salts, a total of 36.20 grains per gal. of sodium salts where there originally was only 2.60 grains per gal. This is the basis of the claim which Mr. Applebaum brands as false.

And, as is well known, the carbonates are the most notorious of all sodium salts in causing foaming, not to mention that when introduced into the modern high-pressure boiler they have been known to break up, forming volatile organic acids which have caused destructive corrosion in pipe lines and in steam-consuming equipment.³

There are a number of other points in the article which are not compatible with the writer's experience in the purification of water for boiler feed, notably those concerning the baking of sludge in the boiler, where his contention is impossible without criminal negligence in blowing down, on account of the levigating

effect of the racing circulation of the water in the boiler; the fact that he exaggerates the disadvantages of boiler compounds, thereby attaching to these disadvantages greater weight than they possess; and he denies the existence of certain advantages which an impartial steam expert will concede to them; and the fact that he minimizes the importance of the disadvantages which practical experience has taught are impossible of elimination in the use of the zeolite system in treating water for boiler feed.

It is really regrettable that an article of so much unquestioned merit should have contained these few glaring discrepancies; and after attempting to correct them, I wish to congratulate Mr. Applebaum upon an article which was highly interesting and genuinely instructive.

The Slip Interference Theory of the Hardening of Metals

To the Editor of Chemical & Metallurgical Engineering

SIR:—The complete solution of the difficult problem of the hardening of metals cannot be very far off now. In the recently published paper¹ by Jeffries and Archer mentioned above the authors in a very meritorious way drew up the principal lines that undoubtedly must be followed to a clear conception of the phenomena of hardening.

The question is very important and has been dealt with in a scientific manner as long as there has been theoretical metallurgy. Jeffries and Archer do not give any account of previous investigations on the matter. Surely it would have been a difficult enterprise to give a lucid review of the many developments in this field of research, considering the great number of rather obscure speculations and theories put forth in the course of time on this matter. However, by reviewing former researches the authors should certainly have found that ideas similar to their own have been suggested before, even if the hypotheses have not been nearly as fully comprehended and ably presented as in this new paper.

F. C. Thompson² in 1916 drew the attention to the disturbing effect that atoms of a substance in solution certainly have on the space-lattice of a metal. He was also well aware of the influence of this distortion on the hardness of the solid solution, even if he ascribes the hardness to those rather problematic and unproved internal stresses in the metal—stresses about which there has been so much written.

Another very clear conception of the great importance of the influence of foreign atoms in a space-lattice has been put forth by C. Benedicks³ in 1916. Possibly Jeffries and Archer are not familiar with this contribution, as it is part of a paper concerning metallic conduction of electricity. To show how very similar the ideas of the American authors are to those of Benedicks a paragraph may be quoted from page 390, on the hardness of martensite:

"This enormous influence on hardening can evidently be accounted for, even if the phenomena of allotropy are taken into consideration, if we might suppose that one single foreign atom has the power to lower the possibility of sliding displacements and

to act like a 'key' for whole planes (like a grain of sand on a rubbing surface in a machine)."

A few weeks ago a very interesting article on the hardness of solid solutions has also been published by W. Rosenhain,⁴ who on the whole has the same views on this matter as Jeffries and Archer.

The reason why former attempts to solve the hardening problem have not been successful may probably be attributed to the fact that the phase rule hitherto has been such a dazzling loadstar to metallography. Investigators on this research field have been so accustomed to the habit of thinking in diagrams that they have not paid sufficient attention to the fact that the various phases are built up of a manifold number of crystals, every one with a certain architecture of atoms.

In the first decade of this century the real existence of atoms has been proved. In the following years it was shown by Laue and Braggs that the atoms in crystals are arranged in regular space-lattices. Problems covering the internal structure of crystals have come into the focus of scientific interest, thinking in terms of diagrams by metallographers begins to give place and will yield still more to thinking in terms of atoms.

Jeffries and Archer have certainly been led to their conception of hardening by their dealing with X-ray analysis of metallic phases. I have also made some X-ray spectrographic investigations of metals⁵ and have come to the same conclusions regarding the hardness of solid solutions as they. In principle I completely agree with them. In a few points, however, my opinion differs from their views.

I do not think the reasons presented for saying that carbon in martensite is dispersed in the form of atoms are quite convincing. I am more inclined to believe that martensite really contains cementite in the form of Fe_3C molecules, and even as very small Fe_3C crystalline grains. The chief reason that Jeffries and Archer put forth for their assumption is that it is impossible for carbon atoms to migrate freely in the metal if they are in contact with particular iron atoms. The authors have evidently overlooked the fact that each carbon atom can very well be connected with three iron atoms and yet easily travel in the metal, since during the displacement it merely changes its companions. If one supposes that there is Fe_3C present in martensite, the very great hardness of martensite as compared with austenite follows in a very natural way. Molecules or grains of Fe_3C certainly act as more efficacious keys, producing slip interference in the ferrite crystals, than could free carbon atoms. I do not wish to go deeper into this matter now; the question can be further elucidated experimentally.

Indeed there are still other points that I would like to discuss with the American authors, such as the influence of amorphous metal, which I think has been very much exaggerated, but it would be better to wait for experiments to decide whether my opinion is right.

Last, I wish to congratulate Dr. Jeffries and Mr. Archer most heartily upon their excellent paper and to record my very firm conviction that a final solution of the hardening problem certainly will diverge very little from the assumption given therein.

Meeting of the American Society for Steel Treating

Varied Social and Technical Activities at the Indianapolis Convention — Some Important Papers on Carbonizing, Heat-Treatment of Ordnance, Manufacture and Properties of Tool Steel, and Theory of Hardening, Abstracted From a Great Wealth of Material

INDIANAPOLIS royally entertained the third annual convention of the American Society for Steel Treating during the week of Sept. 19. In fact, if any criticism should be leveled against the local members of the society it was that they entertained somewhat too lavishly. Mr. and Mrs. George Desautels, acting as chairmen of the members' and ladies' entertainment committees, certainly spared no effort and scarcely left breathing time for their guests. In addition to the usual smoker and banquet, auto trips, teas and such familiar events, the Steel Treatingers and their friends—numbering in all some thousands—beheld a special race on the Indianapolis Speedway, certainly something which only Indianapolis could produce. Ten or a dozen "speed kings," whose names doubtless would be very familiar to racing fans, donned their goggles and helmets and thundered around the track at 100 miles an hour. It was a real Roman holiday and furnished even the exquisite thrill of a car running wild over the top of the embankment, crashing double fences into kindling wood and furnishing the surgical ward with two more patients.

MEMBERSHIP AND FINANCIAL STATUS—NEW OFFICERS

Prof. A. E. White, of the University of Michigan, the retiring president, called attention to the fact that the present membership is 3,237, an increase of approximately 500, or 18 per cent, in the past year. Local chapters also increased by four, the present number being thirty-one. Financially the society is in excellent shape, having no unpaid obligations whatever, while the cash on hand was increased about \$6,000.

F. P. Gilligan, of the Henry Souther Engineering Co., Hartford, Conn., was elected president of the American Society for Steel Treating for the year 1921-22. F. C. Lau and R. J. Allen are the new vice-presidents, J. V. Emmons the treasurer, while W. H. Eisenman retains the post of secretary.

One of the features of the Steel Treatingers' conventions is the daily conferences between national officers and the representatives from each of the local organizations, or "chapters" so called. Many phases of the society's affairs are discussed, with the view of making a determined effort to shape this organization's activities in the correct way. It has made great progress already, and it is not too old to learn.

The exhibits of steel-treating equipment were held in the Manufactures Building at the State Fair Grounds and the technical meetings in the Women's Building, just alongside. In view of the business depression the displays on the whole were not very elaborate, but sixty different concerns manufacturing furnaces, pyrometers, tool steels, carbonizing equipment and heat-treating accessories were represented. Transportation between downtown hotels and somewhat distant Fair Grounds was adequately handled. The attendance was good, especially at the technical sessions. These

were twelve in number, at which no less than eighty-two papers on various phases of metallurgy and metallurgical equipment were presented, either in whole or by title. Printed abstracts of all of them were available, however. A very unusual amount of interest was displayed at these meetings, but the crowded program prevented much discussion. A number of papers are abstracted in these columns. Unfortunately, however, manuscripts of some very important contributions were not available, but they will be printed at length in the society's monthly *Transactions*.

Session on Case-Hardening

The convention opened its technical sessions on Tuesday with a number of interesting and valuable papers on carburizing.

S. C. Spaulding, metallurgist for the Halcomb Steel Co., Syracuse, N. Y., first presented the voluminous results of a research on the comparative rate of carbon penetration in various commercial steels whose chemical analyses are listed:

Group	Alloy	Alloy Content	Carbon
1	{ Cold-rolled		0.15
	{ Hot-rolled		0.20
2	{ Cr:Si:Mn	0.83 : 0.31 : 0.78	0.16
	{ Cr:V	0.92 : 0.17	0.17
3	{ 3½ per cent Ni	3.5	0.16
	{ 5 per cent Ni	5.29	0.14
4	{ Cr:Ni	0.98 : 3.14	0.18
	{ Cr:Ni	1.31 : 3.79	0.11
5	Cr:Mo	0.96 : 0.48	0.13

Three-fourths-in. rods were turned, and one specimen of each was packed in a single box, using a commercial carbonizer. A dozen or more such boxes were put into a large furnace, brought to 1,600 deg. F., and a pair of them removed after 5 hours, 10 hours, and so on up to 60 hours. A second run was made at 1,700 deg. F. After cooling in the pots a wafer was cut from one end, split, polished, and the depth of case measured by microscope, estimating distances to the place where carbon was 0.50 per cent. Typical results follow:

Time, Hr.	Penetration			
	0.15 C		3½ per Cent Ni	
	1,600 Deg. F.	1,700 Deg. F.	1,600 Deg. F.	1,700 Deg. F.
5	0.019	0.029	0.022	0.037
15	0.039	0.052	0.052	0.070
30	0.053	0.075	0.077	0.096
50	0.060	0.095	0.092	0.111
	First Cr:Ni		Cr:V	
	1,600 Deg. F.	1,700 Deg. F.	1,600 Deg. F.	1,700 Deg. F.
5	0.023	0.040	0.023	0.041
15	0.058	0.089	0.051	0.072
30	0.090	0.131	0.075	0.100
50	0.111	0.150	0.086	0.107

Results on penetration and microstructure can be grouped as shown in the first table.

Group 1. Both carbon steels gave time:penetration curves of exactly the same shape, the cases in the hot-rolled being somewhat deeper probably owing to its much lower phosphorus. A cementite network appeared at the edge, inclosing very large grains of pearlite; then a zone of pearlite, then carbon decreasing to the original stock.

Group 2. These curves were about the same up to 40 hours. It seems that 0.17 per cent V, which is the only material difference, had no effect on carbonization. Cementite appeared as rounded masses—there was no network or large grain growth.

Group 3. Nickel retards cementation; this is especially noticeable in the 5 per cent Ni sample. The 3½ per cent Ni sample showed a fine lacy network at the edge, the cementite accumulating into small spots after being carburized a long time at 1,700 deg. F. No network was observable in the 5 per cent Ni sample. The original material possessed a very pronounced banded structure characteristic of many rolled products, and the carbon penetration favored certain of these bands very markedly.

Group 4. This combination, chromium:nickel, seems to be of unique benefit to carbonizing, and these samples gave the deepest cases. They are air-hardening, and the outer edge was austenitic, containing excess carbide as large patches at the border. As the carbon decreased, the ground mass became martensitic, troostitic, and on down. The case preserved the banded structure very clearly; high-carbon bands appeared to replace the original low-carbon streaks.

Group 5. This steel was run at a different time, using the Cr:V of group 2 as a check. Cr:Mo gives slightly deeper penetration than Cr:V, but is associated with a wide cementite network containing many sizable accumulations of carbide. No banded structure remained of this very pronounced condition in the original metal.

Each of these steels was given the appropriate single and double treatment recommended by the S.A.E. specifications, furnishing a mass of data not easily compressed. In general, however, the alloy steels are more easily refined than carbon steels in a single treatment, and give better microstructures after the double treatments.

WOOD CHARCOAL AS CARBONIZER

Although wood charcoal is not looked upon with favor as an agent for case-hardening, H. Schagrin, chief chemist of the U. S. N. Ordnance Plant, Charleston, W. Va., described a commercial operation where it had proved very satisfactory. The parts hardened were forgings about 12 in. long made from acid bessemer steel analyzing C 0.15, Mn 0.70, S 0.05, P 0.06, forgings cheaply made and requiring cheap treatment. Unscreened charcoal up to 30 mesh was used, attempting to place 1 in. of the material between pieces, the cover pressed down and luted, exactly as in ordinary practice. Three of the boxes in each furnace load contained thermocouples, and one of them a "spy" which the furnace tender could withdraw and judge the heat visually.

On being drawn it was often found that one-quarter of the charcoal had burned, due to infiltration of air, but very seldom did this spoil the bright silvery color on the metal. An hour and a half at 1,900 deg. F. gives good carbon penetration to a depth of $\frac{1}{8}$ in.; each 50 degrees above this point makes a great difference in the

depth and character of the case. Experimentally it was found that a carbonization in wood charcoal must be performed at above 1,750 deg. F. or no appreciable result will occur in a few hours' time. The charcoal was forked and re-used, although its consumption was heavy.

For conditions as existing at that plant—i.e., a mass of cheap parts to be given a thin case, with carbon no higher than 1 per cent—the author would recommend wood charcoal as a cement, allowing 1½ to 2 hours at 1,900 or 1,925 deg. F. Two runs can easily be made per shift.

HARDENING WITH CYANAMIDE

Prof. Richards read a paper on the Shimer Case-Hardening Process before the 1919 winter meeting of the Mining and Metallurgical Engineers. The inventors now give some further data on its operation, as perfected by five years' experience. It may be remembered that a bath of CaCl₂ and NaCl (known as "Meltite") is first prepared, and first-class, hard cyanamide (known as "Cyrok") immersed by a weighted basket. Soon a rapid evolution of gases occurs, bursting into small yellow candle flames at the surface of the pot, this continuing for some hours—as long as the bath is active, when, of course, new cyanamide must be added. The gases analyze 70 to 80 per cent N₂ and the remainder CO plus a little CO₂. No CN has been found by analysis, nor is there any cyanide odor noticeable.

Cyanamide air-slakes, and the fine material must be carefully removed in order to prevent frothing in the bath. It should also be handled with gloves. "Meltite" is also hygroscopic, and must be stored in tight cans. It melts at 1,150 deg. F., and while the usual operating temperature is 1,425 to 1,450, it can be heated to 1,700 deg. F. without unusual volatilization. At the latter temperature it produces a $\frac{1}{2}$ -in. case in 2 hours.

It is necessary to dip the finished metal in hot soda ash solution, since any speck of CaCl₂ remaining will facilitate corrosion.

Comparative carburizations in cyanamide and cyanide have been made, and it is found that the former consistently puts higher carbon and lower nitrogen into the metal. For instance, a steel containing C 0.09, Si 0.18, S 0.04, P 0.01, Mn 0.40 was case-hardened 1 hour at 1,526 deg. F. (830 deg. C.) and analyzed with the following result:

	—Cyanamide—		—Cyanide—	
	C	N	C	N
1st cut 1/200 in.....	0.75	0.30	0.62	0.35
2nd cut 1/100 in.....	0.24	0.04	0.27	0.08
3rd cut 1/100 in.....	0.16	0.04	0.11	0.03

CYANIDE HARDENING

Observations on the time of penetration in three different cyanide baths were made by V. E. Hillman, metallurgist of the Crompton & Knowles Loom Works, Worcester, Mass. The process is ordinarily used to give a very hard thin case on pieces made on screw machines. Ordinarily a mixture of about 27 per cent NaCN, 18 per cent NaCl and 55 per cent Na₂CO₃ is used, the latter two raising the melting point of the mixture, and thus counteracting the loss in speed of work due to low concentration of the active cyanogen. The more concentrated cyanide baths must be run at a considerably lower temperature.

A quenched case is composed of two distinct rings; the outer one of martensite and a narrow inner one of

troostite; the center of the latter was taken as the depth of penetration. Results follow:

Time, Minutes at	Penetration in Inches		
	27 per Cent NaCN at 1,475 Deg. F.	76 per Cent NaCN at 1,425 Deg. F.	98 per Cent NaCN at 1,375 Deg. F.
5	0.010	0.010	0.015

Heat-Treatment of Ordnance

Commander W. F. Leary, U. S. N., presented an interesting paper on the heat-treatment of steel for ordnance purposes, in which he ascribed a great part of the improvement in guns, armor and projectiles to the development of proper heat-treatment. Whereas it was formerly necessary to rely on the skill of the workmen, it is now recognized that sound ingots, preliminary annealing, prevention of grain growth after forging and preliminary machinery before forging are essential to prevent failures during heat-treatment. Recording pyrometers and all the ordinary precautions of heat-treating are now liberally used, and a definite and minute program of operation is studied and laid down in advance. Without this practice the 16-in., 50-caliber gun would have been impossible.

Ordinarily, specifications list the physical and chemical requirements in detail and only general notes on heat-treating designed to prevent gross mishandling. Shock tests should also be added, since the finished material before acceptance is tested severely, often by methods developing severe impact.

Castings of plain carbon and nickel steel are much used. Close inspection during manufacture prevents acceptance of pieces with blow-holes and other flaws and also insures correct melting practice for material which will heat-treat properly. Test coupons must be cut from the body of the casting itself to be of real value.

Specifications for gun forgings fill a small book. Numerous paragraphs cover raw materials, melting and ingot practice, so that it would be relatively easy to heat-treat to pass the physical tests. While the process is not specified, the acid open hearth and electric furnaces seem to give the surest results. Sulphur, phosphorus and copper maximums are the only chemical requirements. Physical requirements are between the following limits:

Tensile strength	86,000 lb. per sq.in.	95,000 lb. per sq.in.
Elastic limit (by extensometer)	46,000 lb. per sq.in.	65,000 lb. per sq.in.
Elongation	18 per cent	18 per cent
Reduction in area	30 per cent	30 per cent

These limits are very easy to meet in small pieces, but very difficult in forgings weighing tons. Four transverse test specimens are slotted out of each end, to cover outer, middle and inner portions; in case of failure a check test-piece is taken from that vicinity. Repeated failures cause rejection of the forging. Ghost lines and other segregations are usually associated with irregularity in test results, although it is improper to say that static tension or bend indicates that a ghost-line structure is itself detrimental.

Streaks or ghost lines are generally surrounded by good metal, and the factor of safety in the design is so large that in the case of large forgings their specific effect is greatly masked and difficult of appraisal. Many rejections, however, have resulted from this cause, because such flaws are considered evidence of the doubtful value of a forging. Ghosts are of two classes, one with fine sorbitic grains and much ferrite, the other with large sorbitic grains and absence of ferrite. Inclusions (probably manganese sulphide and silicate) may often be seen with the naked eye in these streaks—close microscopic examination always show them. If they are segregated, the metal is highly suspicious. It is now thought that minute specks of iron oxide are most detrimental to the steel; these, settling in the ferrite boundaries, weaken the adhesion.

Reduction in forging is at least half. The reduced bars are then usually given a preliminary anneal above A_c , (cooled in the furnace to 600 deg. F.) and an examination to insure a normal uniform structure. Rough machining removes that metal which shows no ferrite at grain boundaries, and the desired properties may generally be obtained by a simple quench and draw. A second and higher draw may be necessary if the test specimens show a uniformly great hardness. Structure is generally sorbitic, with grain boundaries plainly marked with uniformly distributed ferrite, considerably increased in amount toward the center. Sometimes needles of ferrite penetrate the grains along a geometric pattern; while this is not considered desirable, it is not reason for rejection. Successful metal can be bent 180 deg. flat without fracture.

Armor piercing projectiles of alloy steel are subjected to very extensive treatments, the details of which are held secret. Forging is done at a low temperature to prevent grain growth and a preliminary normalizing anneal given. After rough machining, the shell is given a series of oil quenchings and drawings for utmost grain refinement and production of "fiber." Hardening the point is done by a graduated heating by dipping the point in molten lead, and quenching in agitated cold water. The base is then reheated to a lower temperature, and suspended, nose down, in agitated cold water, thus tempering the rear only. The projectile point is covered with an alloy steel cap whose heat-treatment is similarly complex.

FORGING AND HEAT-TREATING AT WATERTOWN

F. C. Langenberg, director of laboratory and superintendent of foundry, Watertown Arsenal, explained the methods in use at that place. This work is of great variety, and includes much investigative work on new gun mounts and new high-strength forgings. Since these are all different, it is necessary that closest control be exercised, so that there may not be rejections of some important forging with consequent long delay, or doubt as to its exact history.

After the order for a certain job is received the engineering division makes the design, which of course involves selection of the strength and ductility figures. Then, after consultation with the foundry, metallurgical department, forge shop and machine shop, a forging sketch is prepared, showing the dimensions of the finished specimens, the dimensions after rough machining ready for heat-treatment, location of test specimens, and specifications for strength.

The planning division then routes the work, calling

upon the metallurgical division for information as to the size, weights and composition of the ingots required. If new ingots have to be made, they are ordered from the foundry, after a consultation with the foundry and metallurgical departments has determined the best chemical composition and melting and pouring practice. All of these steel-making operations, as well as the finished ingots, are inspected and carefully recorded by the metallurgical department. Inspection after forging is done by the inspection division; if defects are noted, they are reported to the metallurgist.

The accepted forging is then sent to the annealing department, and heat-treated exactly as specified by a chart of instructions. Then after machining to the heat-treating dimensions, and a second inspection, the forging is sent to the heat-treating shop, which has previously received all instructions as to the treatment desired on a drawing. This shows a complete time-temperature curve covering the entire treatment, and also the nature and temperature of the quenching medium.

The metallurgical division now makes the tests specified (these now include impact tests), and decides whether the piece is acceptable or whether a re-treatment is necessary. Then the inspection division makes its examination, and the accepted forging is shipped to its destination.

If trouble occurs anywhere between steel making and final loading, this close and continuous planning and inspection locates the blame quickly and precisely. Since each department foreman has been consulted regarding all features affecting his work, he is less apt to attempt shifting blame for poor results.

CARBURIZING ARMOR PLATE

W. I. McNerney, of the Armor Plate Department, U. S. N. Ordnance Plant, Charleston, W. Va., presented a paper on the carbonizing of heavy forgings. The plate is forged somewhat thick, and replaced while hot to cool in an annealing furnace. All scale is removed from the plate, and any seams or surface imperfections are chipped out.

If only a thin case is required, say $\frac{3}{16}$ in., a plate is preheated to 1,500 deg. F., removed from the furnace, a 2-in. blanket of carburizer spread over, and the whole covered with a 3-in. layer of dry yellow clay (through $\frac{1}{4}$ -in. mesh). The plate is then slid back into the furnace and heated for time and temperature known to give the desired results. Carburizers used for all this work are purchased (not home made) and must not burn off while being applied, flux with the clay or stick to the metal.

Heavy cases are made by heating plates in pairs, sandwich fashion, with 3 or 4 in. of carburizer between. The bottom plate will have an angle-iron frame attached around its edges, supporting a two-course brick wall to confine the granular material. Four pairs of such plates weighing up to 600 tons have been treated at one time in car-bottom furnaces 15 ft. wide and 52 ft. long. Such practice builds up the following cases in 0.28 C alloy plates:

Time, Hr.	Carbon at Depth			
	$\frac{1}{16}$ In.	$\frac{1}{2}$ In.	1 In.	$1\frac{1}{2}$ In.
24	0.90		0.28	
120	0.96	0.59		0.30
240	1.00	0.69		0.35

Lighter sections (up to 5 in.) are often carburized while preheating for final forging. After having been

raised to 1,500 deg. F. (requiring 12 hours), the piece is covered with carburizer, raised to the forging temperature (requiring 10 hours) allowed to soak for 24 to 30 hours. Carbon analyses resulting are at $\frac{1}{2}$ in. depth 0.90, $\frac{1}{4}$ in. 0.98, $\frac{1}{8}$ in. 0.80, $\frac{1}{16}$ in. 0.60, in a plate having C 0.50, Cr 2.10, Ni 3.50.

It is not usual to "fire back" the plate before stripping and after the completion of the carburizing treatment. Rather the furnace is stripped, and carburizer dumped. The heavy scale on the exposed surfaces falls off as the plate cools to about 1,500 deg. F. The whole plate is then covered with a protective layer of buckwheat coal, a layer of dry yellow clay, and heated for the final forging operation.

Tool Steel

M. H. Medwedeff, of Baltimore, Md., presented a short paper emphasizing correct hardening room practice—points which are well known, but often honored by their breach. It would be well to bear in mind at all times:

1. Anneal thoroughly before hardening, to remove any forging or machining strains. There is no short cut for this operation. Pack the tools in powdered charcoal, heat slowly to 1,500 deg. F., hold from 2 to 4 hours, depending upon the mass, and cool in the closed furnace.

2. Preheat the tool slowly, else exposed corners will be a long time at the high hardening temperature, with corresponding grain growth. In quantity work it is well to have three furnaces, one at 1,150 deg. F. kept filled and used as a stock furnace. Next is a furnace holding not more than three tools, kept at 1,525 deg. F. Next is the high temperature furnace (2,200 to 2,400 depending upon the steel) in which a single tool remains only a few minutes before being quenched.

3. Do not harden tools if you are color blind unless you use a first class optical pyrometer constantly. The thermocouple merely tells you the temperature of a particular spot in the furnace; color comparisons are the best way of judging whether the tool is as hot as the thermocouple.

AMERICAN VS. ENGLISH CRUCIBLE PRACTICE

An extended paper by T. Holland Nelson, steel works manager of Henry Disston & Sons, Philadelphia, Pa., gave a detailed discussion of the crucible melting practice in England and America. Whereas abroad a simple coke hole is still used for 90 per cent of their tool steel and produces three rounds (since the war but two) of metal per day, here regenerative gas furnaces operate continuously, furnishing six heats per 24 hours. There they use fragile clay crucibles, costing 60c. each and good for a day's run, while here we use tougher and larger plumbago crucibles costing \$5 each. Furnace output for a 12-hole furnace there amounts to 3,200 lb., while in America the production is 18,000 lb. Carbon variation in the clay crucible is quite small—it can be held as low as 0.06 per cent. Due to variable graphite consumption, steels from individual crucibles here vary as much as 0.30 per cent.

It is therefore necessary for Americans to teem all their pots into a mixing ladle, casting ingots from the latter. Thus a more uniform analysis is obtained. English steelmakers are as a rule still advocates of the advantage of hammering the ingot to a bar. This is done at a minimum temperature, and great care used to prevent surface decarbonization. Here we use rolling

mills almost exclusively, a practice which is not equal to the other, principally due to the fact that tonnage production seems to insist upon high rolling temperature and heavy drafts. Furthermore, English toolmakers still insist that the more Swedish iron they put in their crucibles the better the resulting steel—a contention the author unqualifiedly indorses, on the ground that no other known raw material is its equal.

TREATMENT OF TOOL STEEL IN THE MILL

A. M. F. Green, chief of laboratory, the John Illingworth Steel Co., agreed with Mr. Nelson that hammering was much better than rolling for reducing high-speed steel from ingot to bar. Hammering is usually done in two heats; first the cogging, then the finishing. Both these operations are started at moderate temperature, the working continued in the first case nearly to A_r , while in the second heat light work may be continued at will to a lower temperature, thus producing more exact sizes and a stronger bar. The correct temperature may be determined by the gain in magnetism, or the greater adherence of scale below the transformation. Cooling from both hammerings is done in lime or ashes, so that a certain annealing effect results.

Rolling, on the other hand, is done from a single high heat, and the finishing temperature is less under control. Hot finishing results in large grains; high heats mean decarburized surfaces.

Normalizing, annealing, or both are necessary if the steel is to be shipped in the best condition. The former is especially necessary to break up banded structure in chromium steels. The correct structure is that in which complete spheroidization of the carbides has taken place. This is an extremely difficult thing to produce if the steel has a structure of great crystals such as caused by high temperature annealing or finishing. Veins of cementite making sorbitic grains in a piece of high-speed steel are indications of especially bad mill practice.

TENSILE STRENGTH OF HIGH-SPEED STEEL AT HIGH TEMPERATURES

A. H. d'Arcambal, metallurgist for the Pratt & Whitney Co., Hartford, Conn., has continued his studies of high-speed steels at ordinary and high temperatures, and at this meeting presented results on two steels of accepted composition:

Steel	C	Cr	V	W
A	0.63	3.55	0.97	17.04
B	0.65	3.33	1.78	13.85

First, transverse tests were made to determine the best heat-treatment; $\frac{1}{2}$ -in. turned bars, 7 in. long, were treated and then ground to $\frac{3}{16}$ in. Hardness was tested with flat temper-testing Nicholson XF files. A series of bars showed that the greatest fiber stress on transverse rupture, together with requisite hardness, is had on either steel after quenching from 2,350 deg. F. in a lead bath at 1,100 deg. F., cooling to room temperature, and drawing back to 1,100 deg. F. If the final drawing was omitted, the test-bar developed many grinding cracks. Those which could be tested gave only half the strength of the tempered bars.

Grade B showed slight coarsening of grain on the fractured surfaces and probably should have been quenched at 2,300 deg. F. Under the microscope, quenched steel showed polyhedral austenite, with nearly all the original free carbides and tungstides dissolved.

Grade B requires a higher draw to remove this polyhedral structure, a little remaining at 450 deg. F., a condition associated with very low strength under transverse test. Both steels give a full martensitic structure after 1,100 deg. F. draw.

Steels of the same class were tested in tension at high temperatures, turning specimens 11 in. long from $1\frac{3}{8}$ in. bars, hot rolled and annealed. Two inches at the center was reduced to 0.505 in. in diameter, the test-piece quenched in oil from 2,350 deg. F. and drawn at 1,100 deg. F. A thermocouple was wired to the center of the piece and the specimen mounted in the testing machine so it extended through an electric tube furnace. After holding at temperature for 30 minutes the specimens were pulled.

Temp., Deg. F.	Strength of	
	Grade A	Grade B
100	243,500	215,000
400	256,500	
600	287,500	273,750
800	285,000	260,000
1,000	240,000	223,000
1,100	220,000	200,000
1,200	185,000	160,000

Fractures of Grade A were all of the usual velvety nature. Grade B gave coarse crystalline fractures, possibly due to undissolved carbides. All except those pulled at 1,200 deg. F. remained hard to the file.

Either steel A or B when tested without a high draw is soft to the file until the temperature at fracture attains 1,100 deg. F. In view of the tendency to omit the 1,100 deg. draw this fact is important. An undrawn tool put into use will often run at temperatures of several hundred degrees F., but will be handicapped by being softer than though it had originally been tempered sufficiently to develop the martensitic structure.

None of the samples showed any measurable elongation or contraction. It is worthy of note that properly hardened and annealed high-speed steel attains its greatest strength at about 600 to 700 deg. F., much like plain and other alloy steels.

Steel A quenched, but not drawn, is comparatively weak (175,000 lb. per sq.in.) a figure less than that for hardened carbon tool steel (183,000 lb.).

TUNGSTEN DETERMINATION BY SPECIFIC GRAVITY

A study of the specific gravity and chemical analysis of a large number of commercial high-speed steels was made by A. S. Townsend, chief chemist of the Cleveland Twist Drill Co., Cleveland, Ohio. He finds that if the specific gravity of a clean piece of annealed steel is determined—a very simple, quick operation—the tungsten content can be obtained to within ± 0.30 per cent by the formula

$$\frac{Sp.gr. - 7.82}{0.049} = \text{Per cent tungsten}$$

About half of the error is due to ordinary variation in chemical content other than iron and tungsten, and the remainder is due to variation in structure—slag content and amount of free carbides.

HEAT-TREATMENT OF 1 PER CENT C STEEL

H. J. French and W. G. Johnson, of the Bureau of Standards, presented an excellent investigation of 1 per cent carbon steel, one largely used in tools, dies, bearings and springs, to determine the best combination for strength and ductility. If the steel is to be drawn relatively high, it should be quenched just above A_{c1} . If it

is to be drawn at 1,000 deg. F. (538 deg. C.), maximum hardness and tensile strength are had by previously quenching from 1,550 deg. F. (843 deg. C.), which is nearly up to A_{cm} . Increased time at the quenching heat acts like an increased quenching temperature—i.e., increases hardness, strength and proportional limit, but decreases ductility.

If a strength of 120,000 lb. is desired, a water-quench before drawing is preferred if the piece will stand it, on account of the higher elastic ratio resulting. If higher strength and ductility are desired at the expense of the elastic ratio, oil-quench from just above A_c . In general it is found that a certain draw (especially if low) will give a higher strength if the piece is water-quenched rather than oil-quenched. If the oil-quenched specimens are tempered higher, to give the same strength, they will have a lower hardness.

Good combinations of tensile strength and ductility may be had by high draws, especially if the steel is ground to size after heat-treatment, but the steel has low resistance to impact. Long heatings just under A_c (704 deg. C. or 1,300 deg. F.) result in a decrease of 40 per cent in Brinell hardness, even though there is little or no change in the appearance of the excess carbide.

Steels at High Temperature

An investigation was undertaken by H. J. French at the Bureau of Standards to find a good steel for use in the Haber ammonia process, requiring pressure vessels at 550 deg. C. He now reports on four normalized steels containing about 0.40 carbon, as shown below, and concludes that the chromium:vanadium alloys are the best, because they possess a high limit of proportionality at elevated temperatures, and consequently will not flow like pitch when under load. Test-machine data were recorded with a cinema, as described in CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, p. 131, Jan. 19, 1921.

Steel	C	Mn	P	S	Si	Ni	Cr	V
A	0.38	0.56	0.014	0.013	0.14			
B	0.37	0.67	0.021	0.010	0.20	3.43		
C	0.39	0.59	0.019	0.005	0.23	3.05	0.93	
D	0.37	0.74	0.020	0.023	0.21		1.04	0.17

Breaking strengths (load at rupture divided by reduced area) are given in Fig. 1.

According to Jeffries' theory of equicohesive temperature, the fractures in the steels broken at more than about 550 deg. C. should be intercrystalline, while lower-temperature breaks should be transgranular. Microscopic examination of these breaks failed to reveal any great difference—on account of the fine-grained distorted structure it is impossible to state what is the ruling type.

Theory of Hardening

Prof. O. E. Harder, of the University of Minnesota, presented a clearly written paper emphasizing one aspect of the theory of hardening—i.e., the importance of solution and precipitation as a cause of hardness in steel and other alloys.

A great many alloys can be usefully hardened: carbon steel, many alloy steels, duralumin, and certain Al:Mg alloys. Experiments with them yield many points in common. For instance, well-made annealed pieces, when cooled at a correct rate after an appropriate heating, possess an increased hardness and exhibit a structure consisting of an assemblage of polyhedral crystals,

all alike—in other words, a solid solution. These pieces can be further hardened, sometimes by mechanical work, sometimes by further cooling, sometimes by aging at room temperature, and always at a rapid rate of tempering. This last-mentioned increase in hardness may result in no change in the microscopic appearance. Hardening steel by mild tempering causes distinct change in appearance; further and higher tempering causes a loss in hardness and the final appearance of recognizable crystals of iron carbide.

These facts all conform to the supposition that a substance which existed in the original piece is much more soluble at a high temperature than at lower, particularly at ordinary atmospheric temperature. Further facts confirm this. When a steel is originally heated, there is an absorption of heat and a contraction in volume when the separate crystals merge into one another and form the solid solution. This is exactly what happens when salt and water, etc., form liquid solutions. Carbon steels on slow cooling expand and liberate this heat of solution when the carbide is reprecipitated, as would be expected in a reversible process of solution and precipitation.

However, quenching locks the solute and solvent in a metastable condition. The tendency for the now insoluble solute to precipitate exists, but there is not the necessary internal mobility or plasticity to allow of the atomic rearrangements. Prof. Harder believes that maximum hardness ensues after this condition of false stability has changed into one of actual instability and complete precipitation of the insoluble constituent has

FIG. 1. BREAKING STRENGTHS OF STEELS AT HIGH TEMPERATURES

occurred in the form of the finest possible particles which can exist as separate crystalline entities. It requires several molecules to form these particles: how many is not known, but they are doubtless far too small for microscopic observation. As an instance, quenched nickel steel is austenitic; it is in the metastable state. Further cooling decreases the solubility of the carbide more and more until finally the tendency to precipitate overcomes the hindering forces, and actual precipitation of cementite occurs with the evolution of heat. The microscopic appearance now suggests martensite, and there is a notable increase in hardness. It

should be noted that the metal as a whole is too rigid to permit an appropriate increase in volume required by the combined volumes of solute and solvent; no expansion is observed and the metal is therefore under high internal stress. Prof. Harder considers that the effect of such stresses has not been given the attention its importance warrants as a principal cause of hardness.

The laws of physics indicate that these tiny particles will accumulate into larger ones if given an opportunity. Tempering allows this. Steels change in microscopic appearance and decrease in hardness (decrease in internal strain) as the particles grow. But not all of the insoluble material may have come out at one time. Jeffries and Archer's *critical dispersion*¹ is therefore thought to be that point where the softening effect of crystalline growth becomes of greater magnitude than the hardening effect of continuing precipitation of tardy particles.

Rosenhain² notes that the hardness of solid solutions is greater than that of either constituent and that it is greatest at saturation of the constituents each in the other. On the basis of this general rule, austenite may be regarded as a highly saturated solid solution, and the change into martensite (with further hardening) is an increase in the saturation, due either to a change in the solvent (gamma to alpha iron), a new solute (carbon changing into carbide), or merely a great change in mutual solubility of two unchanged substances with decreasing temperature. This only applies when martensite is regarded as a solid solution; Rosenhain's theory does not cover heterogeneous systems after precipitation has commenced.

The action of alloys in steel or other metals is thought to be principally one of retarding or catalyzing (as the case may be) the processes of solution or precipitation. Thus, in the Al:Cu alloys a compound CuAl_2 forms which is not of use in hardening until magnesium and perhaps some other metals are added which cause a greater difference in the solubility of the compound at high and low temperatures respectively.

These conceptions—that unusual hardness is associated with the presence of an intermetallic compound of variable solubility, and of the effect of additional metals in "catalyzing" the solution and precipitation processes—should be of great assistance in the search for new useful alloys. Binary systems having intermetallic compounds are the most likely ones. If the solubility of a compound does not show great variations with temperature, try whether additional metals in small quantity will not catalyze this phenomenon. Al:Fe alloys are a case in point; at present worthless, they may become of greatest value.

The Pulp Industry of Pennsylvania

The Bureau of Research of the State Department of Forestry, Pennsylvania, has just completed an initial survey of the pulp industry of the state. The capital investment is stated as \$50,000,000, with average annual value of production placed at \$60,000,000. The industry is giving employment to 7,144 persons, with total annual wages of \$12,500,000, or an average yearly wage of \$1,750. In connection with the survey, it is shown that a large amount of wood is imported annually from other states. Very little of Pennsylvania pulp, it is set forth, is utilized for newsprint manufacture.

Consumption of Coal by Principal Uses

The uses of coal are classified in the following summary issued by the U. S. Geological Survey as a portion of its weekly coal report dated July 23. Although the actual tonnages do not apply strictly to other years than 1917, the proportion probably is much the same for any typical year. In commenting on the table, the Survey issues the following comment and warning:

It must be remembered that consumption is not the same as production. Not only must exports and imports of coal be taken into consideration but the flow of coal in and out of storage must be reckoned with. Further, there is great variation in the quantity of coal actually consumed from year to year, depending to some extent on the weather and to much greater degree on the activity of the industries which are the chief consumers of coal.

The proportion of the total coal consumed, taken by different industries, does not vary so greatly, and the percentages shown in the table below are roughly constant from year to year. The table represents in a general way the conditions during 1917, a year of large consumption. The principal changes since 1917 have been an increase in the proportion exported and a transfer of some millions of tons from beehive to byproduct coke. The proportion consumed by the two types of coke ovens combined has undergone little change.

COAL CONSUMED IN THE UNITED STATES AND EXPORTED

(The figures for bituminous coal in this table represent in somewhat generalized form the calendar year 1917; those for anthracite, the coal year ended March 31, 1917)

	Quantity (Net Tons)	Per Cent
Bituminous coal:		
Industrial plants.....	174,600,000	31.7
Public utilities:

	89,850,000	100.0
Grand total.....	640,950,000	

Lumber Value of Pine Trees Not Affected by Turpentine*

The operation of turpentine pine trees does not lower the strength or resin content of the wood. The crude turpentine, or oleoresin, is not drained from a store in the tree, but is manufactured under the stimulus of the wound by living cells in the sapwood immediately adjacent to the cut on the trunk. No turpentine is produced by the heartwood, because all of its cells are dead. The heartwood may be saturated in places with pitch, but this does not readily flow out as does the resin freshly formed in the sapwood. The major part of the tree is not appreciably affected, and the loss due to death of trees or to a reduction or degrading of lumber is very small when the proper method of turpentine is followed; this loss is more than offset by the additional revenue obtained through turpentine.

American Ceramic Society—Executive Meeting

Report of Conference of Board of Trustees, Officers of Divisions and Sections, Members of Committees and Ex-Presidents—Held to Formulate General Program of Activities for Increasing Technical Service to the Clay-Working Industries

PRESIDENT PENCE called a conference of the leaders in the American Ceramic Society at the Commodore Hotel, New York City, Sept. 15-17, for the purpose of counseling together with the new organizing secretary on methods, policies and plans of activities to be entered into for the future growth and service of the organization. The meeting opened as per schedule on the morning of Sept. 15 and Ross Purdy was elected temporary or informal chairman with the privilege of entering into the discussion. Full stenographic notes were taken at this and all subsequent sessions and are available at the secretary's office in Columbus, Ohio.

DEFINITION OF OBJECTS OF SOCIETY

Considerable discussion ensued on the definition of the objects of the society, and it was thought by some members that the aims and methods of accomplishment of them should be set forth in detail. Motion was made by Mr. Barringer and subsequently carried that the definition of the objects of the society be approved as set forth in the constitution—namely, "to advance and promote ceramic arts and sciences by meetings, publications, literature, journals and other activities."

Chart for research organization was then taken up. The term "research" was here used in the broadest sense. Eventually it was agreed that the chart should be considered a grouping of service committees, so organized under the co-ordinating council of committee chairmen that service and activities with outside agencies and associations might be greatly facilitated. This chart does not include any of the committees functioning on the strictly internal affairs of the society. It is thought these will continue to serve as in the past directly under the board of trustees. The chart as finally approved and recommended to the board of trustees of the society by motion carried in this conference was as follows:

The feature of honorary membership for those who by inventions, investigations, organization or artistic developments have merited recognition as having materially advanced ceramic art and science has been neglected for many years. The promotion from associate to active membership has been carried out at times in a careless way. The membership committee is to look up the question of honorary memberships.

The motion was carried that it was the sense of the conference that the board of trustees should scrutinize more closely the status of those to be elevated to active membership. It was further carried that the question of perpetual membership in the society wherein one fee is paid to keep the member's name forever on the roster of the society be referred to the membership committee for consideration and recommendation.

LOCAL SECTIONS

Discussion of redistricting local sections merged into talk of having the society allot dues to sections; the elimination of sections and strengthening of divisions; having permanent headquarters for divisions; types of programs for local section meetings, and development of new membership by meeting with other local bodies like the sections of the American Chemical Society and engineering societies. The motion was carried that the entire question of local section organization be referred jointly to the committee on membership and that on sections and divisions, because the interests of each are involved, with the request that they return a report.

CERAMIC SCHOOLS

The questions of ceramic trade schools, courses in high schools and art schools and clubs were considered together. A successful trade school is now operating at Trenton, N. J. Others are recommended at Zanesville, and East Liverpool, Ohio. Many high schools have art pottery courses, the total number having some sort of equipment exceeding 300. Over 2,000 teachers

CO-ORDINATING SERVICE COUNCIL

Organizing Secretary as Chairman, and Consisting of Four Other Members Appointed by the Board to Serve as Committee Chairmen 1-4

		Committee Members Appointed by	Co-operation With Other Organizations
1. Com. on Research.....	Pure Science.....	3 members appointed by board	N.R.C. div. chem. and chem. tech.; federal bureaus; semi-public, commercial and industrial labs.; universities
	Applied and Industrial.....	1 from each division	N.R.C. div. research extension; N.R.C. div. engineering; federal bureaus, etc.; industrial associations; universities
2. Com. on Standards.....	Definition.....	3 members by board	A.S.T.M. Committees C-I to C-II inclusive and D-I, D-9 and E-I; ceramic societies abroad, industrial associations, federal bureaus, etc.
	Raw Materials Specifications	3 members by board	
	Standardization of Tests.....	1 member from each division	
3. Com. on Geol. Surveys	Specification of Products.....	1 member from each division	N.R.C. div. geol. and geography; U.S. Geol. Survey and state surveys
4. C m. on Sympos'uns, Monographs, Bibliographies, Statistics.....		4 members by board	N.R.C. div. geol. and geography; U.S. Geol. Survey and state surveys
		1 member from each division	National Research Council; industrial associations; federal bureaus; commercial laboratories; universities

This council of committees will have power of recommendation to the board of trustees and will absorb several service committees which are now covering the same work. The purpose of this form of organization is wholly to aid in outside contacts and obtain co-operation between committees.

in the United States are engaged in this sort of work. Motion was carried to recommend that the board of trustees consider seriously the advisability of establishing trade schools and promoting courses in other schools. Frederick H. Rhead is to work up a brief of opinions from authoritative sources on the possibilities

for such action and bring it with above recommendation before the board of trustees.

COMMITTEE ON CERAMIC EDUCATION

The matter of ceramic education is now left to the direction of the instructional force in each university. It may be that the instructors would like to have some means of contact for advice and information as could be provided by a committee of the society. It would be very queer if the instructional force in any university would not welcome the support of a committee whose interest is general and representative of the territory outside the immediate territory being served. This committee could really study the courses, the equipment and the kind of work being done and give sound advice. The motion was carried to recommend to the board that it consider establishing a committee on ceramic education to function independently of other existing committees.

DIVISION OF ORGANIZATION

Opinion was expressed that the white ware division should be devoted to the pottery industry and electrical porcelains and others formed into a separate division. The terra cotta division is co-operating successfully with the National Terra Cotta Society. The new art division is getting under way with a program for the next meeting.

Divisions should each outline their research problems and take them up with others to try to discover the best method of attacking them. As to how they would be undertaken, whether by individual industrial laboratories, fellowships or federal bureaus, would depend largely on the type of problem. The Bureau of Mines, for instance, wants all the help it can get, whether through committees of the American Ceramic Society or other sources. Everyone interested is approached on each problem undertaken. It was decided that society committees could be of valuable assistance in promoting research for the industries in the various agencies.

The motion was carried that recommendation be made to the board of trustees that the matter of issuance of a bimonthly bulletin from the secretary's office be taken under consideration in order to determine if such a bulletin can be issued without great financial burden to the society.

ENDOWMENTS

The society should have some fixed policy regarding endowments. Plans are being formulated for the Ernest Mayer fund, and those who have it in charge desired some general expression from the conference. The consensus was that the board of trustees continue to handle endowment funds and that further ideas may be developed by the secretary's office.

A motion was carried that the secretary proceed through the present committee on European excursion to make arrangements for an excursion to England or Europe that will include all the clay-working industries in addition to the glass works.

ANNUAL CONVENTION

Arrangements of divisional meetings at the annual meeting are unsatisfactory, because a great many members would like to attend the different divisions and hear the papers. They are unable to do so because of simultaneous readings. Papers of general interest

might be given both before general assembly and divisional meetings. Abstracts should be required in order properly to place papers in divisional meetings or the general meeting, or reject them entirely. Reprints would save considerable time at the meetings as worked out by the American Electrochemical Society.

Motion was carried that it be recommended to the board to place a stenographer in each divisional meeting and in the general session to take record of discussions.

After some debate the motion was carried that an exhibition be organized for the annual convention and the society rent space to exhibitors. The exhibits can replace some advertising papers that are now given on the programs. Such papers cannot be eliminated, however, where they deal with engineering data or new developments.

The motion was carried that the society should neither establish a testing laboratory nor act as a clearing house for existing laboratories. Such institutions should advertise in the *Journal*.

CHEMICAL EXPOSITION

The motion was carried that if the board of trustees decides to have a booth at the next Chemical Exposition the matter of having exhibits be seriously considered.

PUBLICITY

Even a technical organization that is as formal as it can be, as dignified as it wishes to be, if it is to be effective, must publish the fact that it exists and the work it is doing. This applies to both internal and external publicity. It was agreed that the best type of publicity was to get news items into other journals. This is a duty of the organizing secretary.

The motion was carried to approve a publicity program involving uses of reprints and inclosures for general distribution; addresses before conventions or other associations, clubs, schools, etc.; and articles for publication in newspapers and magazines.

CENTRALIZATION OF BUSINESS ACTIVITIES

It was carried by unanimous vote to recommend to the board of trustees that the office of secretary and editor of the *Journal* be combined and that for the following year the general secretary shall act as editor.

The consensus seemed to be that the general office of the society should remain at Ohio State University, Columbus, Ohio, for the present, but that when finances permitted it might better be located in a larger business center.

The Brass and Copper Industry in Canada

An official report on the brass and copper industry of Canada in 1919 (the latest statistics to be had) gives the number of individual plants as fifty-nine—thirty-nine in Ontario, twelve in Quebec, three in British Columbia, three in Manitoba and two in New Brunswick. The total capital investment in that year was \$15,054,981, consisting of land, buildings and fixtures, \$3,099,676; machinery, tools, etc., \$3,285,942; materials on hand, stocks in process, etc., \$3,362,238; and cash, trading and operating accounts, etc., \$5,307,125.

Employees numbered 2,778 males and 343 females, to whom salaries and wages aggregating \$3,642,663 were paid in 1919. Employees earning \$30 per week and over numbered 600.

Operation of Fatty Acid Distillation Plants

Equipment of Modern Fatty Acid Distillation Plant—Preliminary Tests on a New Installation—Operating Technique for the Production of Single-Distilled and Double-Distilled Fatty Acids—Yields and Operating Costs

BY OSCAR H. WURSTER

Chemical Engineer, Chicago, Ill.

ECONOMIC conditions during the post-war period brought about a greater expansion in the fatty acid distillation industry than the country has experienced in any previous similar length of time.

In discussing the design, construction and operation of distillation plants with owners and operators many questions have from time to time been asked, the answer to which the writer has thought might be incorporated into one article.

The operation of a "going" fatty acid distillation plant with experienced operators becomes a reasonably simple matter. But to start up a new plant appears less simple to operators only partly familiar with the process. Furthermore, some of the conditions necessary for the smooth and successful operation of the plant are not always easily maintained. For the best results the system must be continuously in equilibrium—proper temperature balances must be obtained.

An inexperienced or partly experienced operator will find it useful to be able to recognize indications that the plant is not running properly, and will be further benefited by a knowledge of how to restore normal operating conditions.

We trust, therefore, that these directions and comments will be useful as simple operating instructions to the beginner, and that they will be found at the same time to be sufficiently complete and comprehensive to guide him in the best and most efficient operation of the plant as he becomes more experienced.

The writer takes this opportunity of thanking several of his friends among distillation plant operators, to whom the first draft of this paper was submitted for criticism, for useful suggestions and further questions.

CONSTRUCTION OF FATTY ACID DISTILLATION EQUIPMENT

Referring to the accompanying figure, the still *A* is constructed of cast iron of sufficient thickness to give it proper strength and to insure its satisfactory wearing qualities. Being built in sections with separate bottom, cover and dome, the bottom, which receives the hardest wear, can be replaced. To facilitate this the still is carried on lugs bolted to the side of the still, leaving the bottom to hang free into the furnace. Present experience indicates the average life of a bottom to be about five years, the still lasting very much longer.

A brick furnace *B* to fire the still externally and to superheat the injected steam is built under the still. This furnace is of such design that the heat is distributed as uniformly as possible over the bottom of the still. The still bottom is designed to give a maximum heating surface. Local overheating of fatty acids tends to burn the stock, increasing the tar yield by decreasing

the yield of good distilled fatty acids and affecting the color and odor of the distillate. The superheated steam is introduced through a manifold, or "spider," with legs provided with openings placed to give a thorough distribution of steam and to circulate the contents of the still to further avoid local overheating.

Coal is at present most generally used for firing. Oil and gas are used in some plants. The latter can be applied more effectively and efficiently, thus the fuel cost is not as much greater as the difference in cost of these fuels would indicate. The greater ease with which the still temperature can be controlled and maintained uniformly is also conducive to higher yields of good distilled product.

The pitch produced in the stills has also been used mixed with crude oil as liquid fuel to fire the still and superheater furnaces. Some of the indirect methods of heating have also been used. There is, however, not sufficient difference in thermal head between the required still temperature and the temperature of the

FATTY ACID DISTILLATION PLANT

fluid heating medium in a system operating under moderate pressure to make this method a success, and when water is used as the heating medium the pressure required on the heating system is so high that further engineering problems are introduced.

A satisfactory indirect heating method—that is, one in which a fluid at high temperature would be heated at some distant point, as in the boiler room, and circulated through a coil within the still—would be very desirable. The temperature control of the still would be improved, there would be less wear on the still bottom, the furnaces and heat would be removed from the still room and fewer and more efficient furnaces could be used.

The surface condensers *D, D* are of the vertical type

and are usually constructed with copper dome, tubes and bottom chamber. The water jacket is steel. Under the condensers are placed copper expansion chambers or receiving eggs *E, E*, in which the condensed fatty acids separate from the vapor. The steam and uncondensed fatty acids pass on, while the liquid flows down to the copper discharge eggs *G, G*. When two discharge eggs are used, they can be shut off from the system alternately, the vacuum broken and the collected fatty acids pumped to storage. When but one discharge egg is used, the fatty acids are allowed to accumulate in the receiving eggs *E, E* until the discharge egg *G* is emptied.

The vapor piping *C* connecting the still, surface condensers, receivers and barometric condenser is copper. All these various pieces of equipment have been built of aluminum also, but under practical operating conditions copper has generally been found to be most satisfactory.

The steam and non-condensable gases passing the surface condensers *D, D* pass on to the barometric condenser *H*. This is usually steel or cast iron and of the counter-flow type, the vapor entering near the bottom and the condensing water near the top. The non-condensable gases and air introduced with the steam and through leaks are taken off the top of the barometric condenser *H* by the vacuum pump *S*, thus maintaining the vacuum on the entire system. A simple rotary type of vacuum pump has in recent years been found to be exceptionally satisfactory, maintaining a uniformly high vacuum, having a very large working capacity and being economical both in first cost and in operation and maintenance.

The hot-wells *K, P* and catch-basins are usually built of concrete. Cast-iron feed tanks *L, L* built in two or three sections and of large capacity are very satisfactory. The tar tank is a steel tank.

Buildings of various types are used, the most satisfactory being those of modern fireproof construction designed to fit the plant.

TESTING EQUIPMENT PRELIMINARY TO STARTING PLANT

In the case of a new installation, the usual precautions should be taken to warm up gradually the furnace brick work. Since the brick furnace can be completed some time before the still will be ready to operate, there is usually ample time to allow the brick work to dry out naturally and then to build a wood fire in the furnace for several days to dry it out thoroughly.

The equipment should be filled with water, tested for leaks under 15-lb. pressure and tightened up wherever such leaks are found. After drawing off the water, vacuum of 26 to 27 in. should be pulled and held on the entire equipment. With the entire installation in good shape, as shown by these tests, the still is ready to be put in operation.

Single-Distilled Fatty Acids

PREPARATION OF FATTY ACIDS FOR THE STILL

The "split" or saponification of fatty acids for distilling purposes should be as high as can be practically obtained—that is, 94 to 96 per cent. The fatty acids, by whatever process produced, should be thoroughly freed, by washing if necessary, of sulphuric acid, calcium sulphate (lime salts) or sodium carbonate and sodium sulphate (alkaline salts). After washing and

settling, the crude fatty acids are ready to pump to the drying and feed tanks. To dry the fatty acids thoroughly, they are heated in the drying and feed tanks to a temperature of 220 deg. F., being agitated at the same time with air. By drying under these conditions, there is positive assurance that no moisture is left in the stock. Feeding water into the hot still (425 to 550 deg. F.) causes the sudden formation of a large volume of steam, in the expansion of which stock is carried over to the condensers, causing discoloration. In other words, the still "primes over." Feeding a large quantity of relatively cold water into the still is also very likely to result in damage to the still bottom. In some of the older plants the fatty acids are not preheated in this manner, but the water is settled out by allowing the fatty acids to stand hot for longer periods of time in large wooden tanks. This requires somewhat more storage capacity and also a greater lapse of time in the preparation of fatty acids for the still. There is at the same time always a possibility of feeding some water into the still with the fatty acids, whereas if all fatty acids in the feed tank have been heated to 220 deg. F. with air agitation, it is impossible to feed water to the still from the feed tank.

CHARGING AND STARTING STILL

Vacuum is pulled on the still, and at the same time about 15,000 lb.¹ of hot fatty acids from the feed tank are fed to the still. This quantity of fatty acids will come to an inch or two of the center of the gage glass, and the level of the fatty acids should show in the gage glass throughout the entire run until running down to tar. Fire is now built under the still. (Never have fire under empty still.) Steam is turned in through the superheater. If the still is cold so that stock fed in on start is cooled below 200 deg. F., the still may be warmed up until the stock shows a temperature of 200 deg. F. or slightly above before turning in the superheated steam. At the same time fire is built in the superheater furnace. The reducing valve on the steam line is set so that the steam goes to the superheater at from 15 to 20 lb. pressure. All of the valves on the superheater sections are set wide open. The regulating is now done on the main valve next to the still. If, to provide for emergency, two valves are placed on this line, the first valve is set wide open and the regulating is done on the main valve next to the still. The same valve should always be considered as the "emergency valve," and therefore, always being wide open or closed, the seat and disk will be free from wire-drawing. The regulating valve is now so set that the steam goes to the still at about zero pounds pressure. (Whether the steam should go to the still under slight vacuum or slight pressure depends upon how the superheater sections are connected. If connected in series so that all of the steam passes through each section, then the steam may go to the still under several inches vacuum. If, however, the superheater sections are connected in parallel so that the steam is divided and a fraction of it passes through each section, then the steam should go to the still either under zero pounds pressure, or preferably 1-lb. pressure, so that the presence of steam in each section is assured, otherwise it is possible to burn out a superheater section.) A small amount of water is turned on to the

¹All figures given which are dependent upon the size and capacity of the still refer to a still 9 ft. in diameter by 17 ft. deep, with 1,000 sq.ft. of copper-condensing surface in two condensers.

barometric condenser. The surface condensers and the steel tanks containing the receiving eggs are filled with warm water.

The still temperature is brought up to about 450 deg. F. and the superheater temperature to about 550 deg. F., as rapidly as possible. As the temperature rises, some steam will condense in the surface condensers and collect in the discharge eggs, and this is blown or pumped out as necessary. Fatty acids will start to distill over at 410 to 425 deg. F. As the system heats up and rapid distillation takes place, it becomes necessary to turn on sufficient water to both surface condensers and the barometric condenser to control the temperatures properly. The water going to all condensers should have a temperature of 100 to 110 deg. F.—that is, the temperature of the cooling water going to the condensers should be slightly above the melting point of the fatty acids being condensed. (If the temperature of the water is taken at the pump on the ground floor or at some other point at a distance from the condensers, allowance must be made for further cooling.) The hot water coming from the surface condensers should be about 140 deg. F. and the water in the down-leg of the barometric condenser should be 115 to 120 deg. F. It is usually found that the cooling water temperatures of the two surface condensers can be so regulated to advantage that the water coming from the first surface condenser will be about 160 deg. F. and that coming from the second surface condenser about 130 deg. F. As the fatty acids distill over, crude fatty acids should be fed to the still to keep the level in the gage glass constant. If it becomes necessary to discontinue feeding at any time because the fatty acid level in the still is too high, then the feed line should be blown out with steam to prevent the freezing of fatty acids in the lines. If the feed tanks are located sufficiently high to get a gravity feed to the still and there are no "pockets" in the feed line, then the vacuum on still will generally draw all fatty acids from feed line if only the valve at the feed tank is closed. Care, however, should be taken that no air is drawn into still through leaks in feed line.

CONTROL OF CONDENSERS

The above condenser water temperatures are given having in mind the distillation of cottonseed oil, garbage grease and similar low titered fatty acids. The practice is to run the cooling water to all condensers at a temperature just slightly above the melting point of the fatty acids being distilled so as to prevent same from solidifying on the condenser tubes. The cooling water should be taken from the surface condensers as cold as possible to obtain maximum condensation of fatty acids, but not so cold that an excessive amount of steam will be condensed with the fatty acids—that is, 130 to 140 deg. F. (The fatty acids as blown from the eggs will contain from 10 to 20 per cent water.) The temperature of the condensing water in the down-leg of the barometric condenser should be as low as is consistent with economy in the use of cooling water, as thereby the efficiency of the vacuum pump is increased.

With higher titered fatty acids, the condenser water temperatures are increased accordingly. With stearine fatty acids, the cooling water is run to the condensers at 120 to 130 deg. F., the overflow from the surface condensers will be 140 to 160 deg. F., and the barometric down-leg will be 130 to 140 deg. F.

It is not necessary to circulate water through the steel tanks holding the receiving eggs. On the other hand, should the water in these tanks become cold, as in between runs, then it should be heated with steam, or the cold water should be run out and replaced with hot water. These tanks should preferably be equipped with a small ($\frac{1}{2}$ -in.) steam line so that the water in them can be at all times maintained at a temperature somewhat above the melting point of the fatty acids being distilled.

STEAM CONSUMPTION AND RATE OF DISTILLATION

One pound of steam, approximately, is required to distill 2 lb. of fatty acids. Instructions were given above how to set the steam valves to start operations. During the first few runs it can be determined if the proper amount of steam will be supplied in any particular installation and under local conditions with the valves set as directed. With still temperatures and steam pressure as directed and other conditions normal, if the still does not deliver its rated output, it is probably due to insufficient steam supply. In starting up a still on crude fatty acids and in redistilling single-distilled fatty acids, 1,500 to 2,000 lb. per hour should be distilled. If, on the other hand, the rate of distillation is high, condenser temperatures maintained by adequate water flow as directed and other conditions normal and an excessive quantity of fatty acid is going to the barometric condenser (as indicated by the accumulation in the barometric condenser hot-well), then it is very probable that too much steam is being turned into the still, with the result that fatty acids are distilling over at a rate exceeding the capacity of the surface condensers to condense same and some of the fatty acids pass on to the barometric condenser. In either case, proper regulation of the steam supply should be made.

COOLING WATER REQUIRED FOR CONDENSERS

Approximately 150 gal. of water per minute per still will be required when distilling at the rate of 1,000 lb. per hour. Since the rate of distillation will at times be much greater than this, correspondingly more condensing water will be required. From one-half to two-thirds of this condensing water is required for the barometric condensers, the balance for the surface condensers, the proportion, of course, depending somewhat upon the temperatures maintained in the surface condensers.

When the still is operating at a maximum capacity, the necessity for a larger quantity of cooling water can be partly offset by running the cooling water to the condensers at a somewhat lower temperature, say 90 to 100 deg. F. This, however, must be done carefully and by an experienced operator, since there is always the danger of freezing fatty acids locally in portions of the condensing system, and such local freezing occasionally results in choking up the entire system by closing the passageway for the gases and vapors.

The freezing of fatty acids in the condensers and serious choking up of the system is usually indicated first by the dropping of the vacuum on the still. Partly solidified fatty acids will show in the sight glasses over the eggs, and the flow to the eggs will gradually cease, the white solid fatty acids showing in the glass. Then, if the condensing system is examined, the vapor

pipe leading to the barometric condenser will probably be found cold and the second condenser may be cold, as well as the vapor line from first to second condenser. It will also be noted that the condensing water will leave a frozen surface condenser at about the same temperature at which it enters. The operator no doubt will note the trouble long before the first condenser closes up. To open the system, the cold water should be drained from the steel water jackets and these be filled with hot water. If an open steam line was connected into the steel jackets in the erection of the plant, it is a simple matter to turn off the water supply and turn on steam until the water boils. The water in the steel tanks surrounding the receiving eggs should be brought to boiling with open steam. The trouble, once discovered, is quickly eliminated. Should the whole system become solidly frozen through inattention, it would probably be advisable or necessary to draw the fires, but such an extreme case has never come to the writer's attention.

The discharge eggs are blown out or pumped out alternately as they fill up. We recommend pumping out the fatty acids from the discharge eggs. Blowing out with air is common practice and is also satisfactory. Blowing out with steam is not satisfactory. A 2-oz. or 4-oz. sample of the fatty acids from each egg should be taken and held for reference. This sample can either be taken at the discharge into the storage tank, or, more conveniently, from a petcock in the discharge line near the eggs.

UNIFORM FIRING INCREASES YIELD

The still and superheater furnaces should be fired uniformly and the feeding to the still should be uniform, as it is only in this way that uniform temperatures and even distillation can be maintained. With careful and sensible firing, about 100 lb. of coal per hour per still will be required for still and superheater furnaces combined. The quality of the distilled product is improved and the yield of good colored fatty acids increased by maintaining a uniform still temperature and even distillation. When operating in this manner, it will be necessary to make only slight and gradual changes in the cooling water supply. Large variations in temperature resulting from poor firing or from suddenly feeding large quantities of relatively cold fatty acids to the still interfere with the smooth and uniform distillation of fatty acids and also interfere seriously with the smooth and proper operation of the still in that it requires frequent changes in the condensing water supply.

During the first run of a new still the several valves controlling the water supply to various points in each surface condenser can be, by careful regulation, so set that they will thereafter require practically no attention, the future regulating of the water supply to each surface condenser being done entirely by the single-control valve in the line feeding the separate supply lines.

LENGTH OF RUNS VARIES WITH PITCH YIELD OF STOCK

When feeding black fatty acids to the still, from 50,000 to 125,000 lb. of stock can be fed to the still before running down to tar, this depending upon the amount of pitch obtained from the material being fed. In the case of fatty acids obtained from cottonseed oil foots, 50,000 to 60,000 lb. will constitute a run, whereas

with fatty acids from garbage grease or low-grade animal fat from which the pitch yield is relatively low from 60,000 to 125,000 lb. stock may be run. The character of the distillate—that is, its color and odor—will indicate when it is time to run down to tar. When the distillate becomes so dark that it can no longer be classed or used as once-distilled stock, there is no object in continuing the run. Feeding to the still is then discontinued. To some extent the amount of stock fed is also controlled by the preference of the operator. Some operators prefer short runs of about 60,000 lb. yielding about 3,000 lb. pitch, with less time consumed in running down to tar.

RUNNING DOWN TO TAR

After the feeding of fresh stock to the still is discontinued, the still temperature gradually rises. The temperature of the superheated steam should be forced up accordingly. After the fatty acids can no longer be seen in the gage glass, samples should be drawn from the tar sampler regularly to determine the consistency of the residue in the still. As the still temperature approaches 550 deg. F. and the superheated steam has been forced up to about 650 deg. F. most of the fatty acids will have been distilled over and frequent samples should be taken from the tar sampler. The first samples taken will be thin and oily. As the temperature rises, the pitch will become thicker, more "rubbery," but on drawing out between the fingers will be "short" and greasy. The point at which the tar should be drawn from the still will be approached when the sample drawn will pull out in long threads and is fairly dry when worked in the fingers. So long as samples can be drawn out from the tar sampling tube, there will be no difficulty in drawing the tar from the still.

Tar from acidulated cottonseed oil foots hardens more quickly than that from garbage grease and animal greases. With the latter stocks, higher still temperatures, from 575 to 600 deg. F., must be reached before drawing pitch. Temperatures above 600 deg. F. are not required to give a hard pitch. If the still temperature rises too rapidly and shows signs of going above 600 deg. F., it should be checked by regulating the firing. When, however, a sample can no longer be drawn from the sampling tube or if the last sample drawn is fairly dry and hard when cold and draws out into long threads when pulled—in other words, is thick and viscid and rubber-like—then the pitch should be withdrawn immediately from the still. As the samples indicate that the pitch in the still is thickening and must soon be drawn from still, no fresh fuel, if coal is burned, is added to the furnaces and the temperature is maintained by breaking up and burning freely the fuel already on the grates. This will leave a relatively small amount of fire in the fire beds when it is time to draw the tar.

DRAWING TAR

The fires are drawn from the furnaces, or the burners turned off if gas or oil fuel is used, the valve on the vacuum line to the barometric condenser is closed and steam is turned on the ejector on the tar tank. The vacuum on the still starts dropping. When the still vacuum is down to zero, or at most 1 to 5 in. and a vacuum of about 20 in. has been pulled on the tar tank, the superheated steam into the still is shut off (and

the superheaters vented to the atmosphere) and the tar cock on the still opened. In making a first run, an inexperienced operator can, by hammering on the 4-in. tar line before drawing tar, familiarize himself with the clear ring of the empty pipe as distinguished from the deadened sound obtained when hammering on the tar line while the tar is running. (The flow of the tar in the tar line can also be felt by placing one end of a pencil on the tar line and pressing the teeth against the other end.)

After the vibration of the tar line ceases, showing that the flow of tar has discontinued, and the tar line rings clear and the vacuum on the still rises and equalizes with the vacuum on the tar tank, then the 4-in. cock next to the tar tank is turned so as to close off the tar tank and open the tar line discharge to the atmosphere. Steam through the superheater is again turned into the still and the still thoroughly steamed out for 10 or 15 minutes. The condensation and tar thus blown out are collected in a barrel placed under the open discharge next to the tar tank. It should be pointed out that whenever steam from the superheater to the still is shut off while there is fire in the superheater, or the superheater furnace is hot, the bleeder to the air between the superheater and the still should be opened so as to pass at least a small amount of steam through the superheater to prevent overheating or burning out.

In some plants it is not the practice to turn off entirely the superheated steam to the still while drawing tar. From 5 to 8 lb. pressure is left on the superheater. The temperatures are so high that the steam is not condensed in the tar, but passes out of the still to the condensers. The manipulation of the still at a time when the operator is extremely busy is thus materially simplified.

REGULATING CONDENSING WATER

No mention has been made of regulating condensing water while running down to and drawing tar. This is optional. Less water is, of course, required as less stock passes over, and the extent of the regulation will be determined by the source of the water supply and the possible economy which may be effected.

After the still has been steamed out, superheated steam to the still is shut off, the tar cock on the still is closed and the still is ready for another run. After the cock in the tar line next to the tar tank is turned so as to shut off the tar tank and vent the tar line to the atmosphere, then the valve on the suction line between the ejector and tar tank is closed and steam turned off of ejector. If the tar is drawn from the still very hot, say above 575 deg. F., the ejector should be left on the tar tank for an hour or so as a precaution to remove gases given off and avoid pressure developing in the tank.

Mention should be made here of the remedy in case it is found that the pitch has become too thick to flow, or has become spongy and cannot be drawn from the still. This is of infrequent occurrence and is apt to be so troublesome that after an operator has had the experience once he is quite likely to avoid a recurrence. The tar cock should be closed again or set for feeding in fresh stock, vacuum pulled on the still and several thousand pounds of fresh stock fed in. The still is fired and run for a short time, following the instructions given above for running down to tar. In

this way the heavy, thick pitch is dissolved and thinned down with the fresh stock, and most of the latter is recovered in the subsequent distillation. While running down to tar the second time and before drawing same, the tar line should be blown out with steam to make sure that the line to the tar tank is open.

If the still is allowed to stand with thick tar in it, several days must elapse before the still cools sufficiently to work in it and then it is an extremely slow and tedious job to dig out the tar and clean the still and steam distributing system.

FILLING OFF TAR FROM TAR TANK

The tar can be drawn from the tar tank any time after several (5 to 6) hours' cooling. If fairly hard, care should be taken not to leave it in the tar tank so long that it will not flow freely. At a temperature of 300 to 350 deg. F. the tar will flow and not froth in the barrels or drums. The tar tank is provided with a small furnace in which a fire can be built to take the chill out of the setting and tank. The fire built under this furnace should at no time be greater than that obtained by burning one or two barrel staves. Too hot a fire may injure the tar tank, since there is no circulation on the inside. In other words, the fire is used merely to warm the setting and tank, to keep cold tar from building up in the tank, and not to attempt to heat the tar after same has cooled. This can be done only by running in a fresh batch of hot tar on top of the cold tar in the tank. The tar is usually filled into caustic drums or tight tierces. Barrels should be dry to prevent frothing and are usually whitewashed by rinsing with limewater to make them strip easily.

The gases given off by the hot tar in the tank are flammable, and together with the air in the tar tank form an explosive mixture. Therefore, do not use a red hot bar to open the passageway through the tar cock, should it become plugged. Use a warm bar, or close the tar cock and build a slow fire under the outlet nipple and cock until same are warm. Remove the fire before opening the cock. If for any reason the manhole cover is removed from the tar tank, no open flame or lantern should be brought near. Do not use air pressure in tar tank to force out the tar.

Double-Distilled Fatty Acids

The general instructions applying to the operation of the still in making single-distilled fatty acids apply to the operation in making double-distilled. The length of the run is, of course, considerably increased, since there is very little pitch (from 1 to 1½ per cent) obtained in running from single-distilled to double-distilled.

PREPARATION OF FATTY ACIDS

In making double-distilled fatty acids, once-distilled fatty acids are fed to the still. As collected from the first distillation, the once-distilled fatty acids contain considerable moisture. This should be allowed to settle out in the storage tank and the clear fatty acids pumped to the feed tank, where they are heated and dried, as described for crude or "black" fatty acids.

The still is started up and operated in the same way as described above for single-distilled fatty acids. Eighty thousand to 200,000 lb. of good double-distilled fatty acids is collected before the distillate darkens to such an extent that it can no longer be classed or

used as double-distilled fatty acids. When this point is reached, the distillate is blown or pumped to the single-distilled fatty acid tanks, and at the same time the feed from the single-distilled feed tanks is shut off and crude or "black" fatty acids are fed to the still. The operation of the still is now continued as described above for single-distilled fatty acids until tar is drawn and the still steamed out.

When a battery of stills is operated, it is customary to reserve certain stills for making single-distilled fatty acids and other stills for making double-distilled fatty acids. In this case, when the distillate is no longer suitable for double-distilled fatty acids, the residue remaining in the still is drawn through the tar line into one of the stills running on crude fatty acids, and the still without any further steaming out is ready to be charged anew with single-distilled fatty acids.

The advantage of this procedure when a battery of stills is being operated is that the operator is assured that no hard pitch is at any time left in the stills which are used to make double-distilled fatty acids. It is to remove any such hard tar or pitch in the still that the steaming out of the still is done in accordance with the instructions given in making single-distilled fatty acids.

With proper control and operation, it is possible to run a still distilling double-distilled from single-distilled fatty acids continuously for a week before drawing the residue over to the "black" still. At times the distillate may show signs of darkening, and one or two eggs may have to be pumped to single-distilled storage, but by easing off on the firing temporarily or feeding in fresh stock, the distillate can be brought back to the proper color.

YIELD OF DISTILLED STOCK

The yield of double-distilled fatty acids varies with the nature of the stock, with the manner in which the stock is handled and with the design and operation of the still. With fatty acids from acidulated cottonseed foots, the yield of double-distilled stock is about 85 per cent. About 12 per cent of pitch is obtained. Garbage grease fatty acids yield about 90 per cent double-distilled stock and 6 per cent tar. Other low-grade naphtha extracted greases will run slightly better than garbage grease, and pressed animal stock will give higher yields. The higher the split or saponification—that is, the less neutral oil left in the fatty acids—the higher the yield of fatty acids. The elimination of impurities by washing improves the yield. Proper design of still furnace, still and steam-distributing system is necessary to give maximum yield obtainable from a given grade of stock. The still must be operated with judgment and with careful, thoughtful attention to details. Air leaks throughout the plant must be avoided. Thus a high yield of superior color without offensive odor will be assured.

GRADING DISTILLED FATTY ACIDS

For color reading the Lovibond Tintometer is most commonly used and the fatty acids are placed in a 1-in. glass cell. Fatty acids acceptable from the color standpoint as "single-distilled" will run 35 yellow, 7 red. Double-distilled fatty acids will run 35 yellow and 4 red. There are no universally accepted standards at the present time. In a plant operated in connection with a soap factory or a stearic acid plant the fatty acids produced are brought up to the requirements of

the kettle or press room, and fatty acids distilled for sale are commonly sold on sample. In the earlier stages of a run double-distilled fatty acids will give a color test of 35 yellow and 2.5 red, or even slightly better.

COST OF OPERATION

The following costs were determined by the writer the early part of the present year in a two-still plant which had been recently installed and put in operation:

COST OF OPERATING TWO FATTY ACID STILLs			
Material and Labor Cost:			
20-hp. water circulating pump motor	} at 2½c. per kw.	\$1.33	
50-hp. vacuum pump motor			
1,000 lb. steam per hour		.50	
300 lb. coal per hour at \$4 per ton*		.60	
1 fireman		.45	
1 still man		.60	
1 helper		.40	
Cost per hour		\$3.88	
Cost per 24-hour day			\$93.12
Overhead, etc.:			
Depreciation per day on stills and equipment, total \$55,000 at 10 per cent per year		\$18.00	
Depreciation per day on building, \$55,000 at 3 per cent per year		6.00	
Interest on investment—building, \$55,000; equipment, \$55,000; land, \$8,000; total, \$118,000 at 6 per cent		24.00	
Insurance at \$150 per year, per day		.50	
Interest per day on inventory of \$75,000 at 6 per cent		15.00	
Overhead per day			63.50
Operating and overhead per day, producing 24,000 lb.		\$156.62	
Operating and overhead costs per 100 lb. D.D.F.A.		.65	

* Note.—The coal consumption was reduced to about 200 lb per hour, or about one-third, after the stills were insulated and the fireman became more experienced.

It will be noted that in this plant the cost of producing double-distilled fatty acids from crude fatty acids is 65c. per 100 lb. The writer knows of no reason why this cost should be any higher in any modern, properly constructed and operated plant. In the plant referred to all equipment is of the most recent and best design and, together with the installation and building, is of the very highest class.

CONCLUSION

In closing, it may be said that from the experience gained by the writer in designing and operating the many recent fatty acid plant installations, it has been possible to make very decided improvements. These apply not so much to the relatively simple basic principle of design, but rather to the perfection of numerous details which facilitate the uniformly smooth operation and proper control of the plant, centralize this control, eliminate unfavorable working conditions, simplify the duties of the operator, prevent damage to the equipment and make all parts of the equipment easily accessible.

The equipment must be substantially constructed so as to eliminate costly repairs and the more serious loss of output incident to shut-downs while making such repairs.

It is the desire of the still operator to obtain the highest possible yield of best quality distilled fatty acids at minimum cost. The writer trusts this paper may assist him in attaining that end.

German Trade With Santiago de Cuba

Imports of merchandise into the port of Santiago de Cuba from Germany in 1920 were valued at \$275,231, and were principally hardware (tools, cutlery and aluminum ware), cement, beer pianos and toys, reports Consul Clum. Dutch vessels carried about 90 per cent, American vessels about 5 per cent and Norwegian vessels about 2 per cent of these imports.

Studies of Crystal Structure With X-Rays

Apparatus for Analyzing Atomic Spacing of Metals and Crystalline Powders, Brief Notes on Its Design, Operation and Interpretation of Results—Known and Potential Scope of the Method Is Discussed

By EDGAR C. BAIN

Cleveland Wire Division, National Lamp Works

IT SEEMS conservative to predict that some very important data will soon be disclosed in the realm of physical metallurgy as a result of crystal study. While in no way encroaching upon the microscope—which has served to clear away much of the mystery surrounding the production of useful alloys and their subsequent mechanical and thermal treatment to develop desirable physical properties—the knowledge of the spacing and character of atomic arrangements in metals may find a more fundamental application.

With large and perfect crystals, the crystallographer has been able to give with surprising accuracy the form and angles of many materials. But metals are opaque and prone to exist as aggregates of polyhedral crystal grains whose contours bear no relation to crystal structure. Less has been accomplished in studying their internal structure except by the uses of X-rays developed by Laue and the Braggs.¹ Largely as the result of further development of this method by Hull,² St. John and others, it is not difficult now to study the crystal structure of almost any material.

Usually the metallurgist has not been inclined to follow out the complexities of X-ray diffraction and interference phenomena, and hence the work has been performed by physicists. But if the prospective investigator does not wish to devote the time necessary to a complete familiarity with the physics of the process, he still may be able to obtain end-results which he can utilize. If possible, he should become acquainted with the development of the method from the first "reflection" of X-rays by planes of atoms to the evolution of the present practices. But even if this is not practicable, he may accept the barest facts of crystal patterns and still derive useful information from his results. The splendid descriptive papers of Jeffries and Archer³ in this journal should furnish him such understanding.

In the author's laboratory the method of Hull² is employed. Effort has been made at all times to simplify equipment to the utmost. Such simple devices as will enable the investigator to determine atomic arrangement will be described here.

SOURCE OF X-RAYS

A universal, broad-focus, molybdenum target Coolidge tube, operated from a high-tension transformer, supplies the radiation. Its connections are shown diagrammatically in Fig. 1. The X-rays may be regarded as a form of radiation differing only in frequency or wave length from Hertzian waves (wave length 10^6 cm. to 0.2 cm.), infra red (wave length 0.031 cm. to $7.7 \times$

10^{-5} cm.) visible light (wave length 7.7×10^{-5} cm. to 3.6×10^{-5} cm.), ultra violet (wave length 3.6×10^{-5} cm. to 5×10^{-6} cm.), or gamma rays (radium radiation, wave length 1.4×10^{-8} to 1.0×10^{-10} cm.). X-rays have been produced which overlap the range of the radium radiation.

On account of the general suitability of the dominant wave length, the lower voltage required and the absence of excessive penetration, the molybdenum target is chosen. For use with some specimens the characteristics of the rays produced by the tungsten target are very suitable, however. To permit use at high capacity the broad focustube is chosen. To shorten exposures, the tube is run at limiting capacity and the sharp focus target would be locally overheated by the desired energy input. The sharp focus tube is chosen by the radiographer to give less confusion in his shadows, approximating as it does a point source.

The Coolidge tube is essentially a vacuum in which an electrically heated spiral filament supplies the available electrons which bombard a heavy target, maintained at a positive potential of several thousands of volts to the filament. This target emits X-rays of various wave lengths as a result of the electronic bombardment. The distribution of intensity in the different wave lengths is controlled by the potential maintained between the filament and the target—the higher voltage giving the shorter wave lengths. The intensity of any particular

FIG. 2. DIAGRAM OF APPARATUS FOR CRYSTAL ANALYSIS

ray is controlled by the temperature of the spiral filament, and this in turn by the filament current.

The transformer should have a continuous capacity of at least 5 milliamperes at 40,000 to 45,000 volts. A small auto-transformer in the primary circuit controls the high-tension voltage. Rheostatic control is poorly suited to this type of work, but could be used with vigilant supervision. The filament may be heated by almost any steady source of 10 to 12 volts, current closely regulated by rheostat. The author finds a step-down transformer most convenient, employing a rheostat control on the primary.

The factor limiting the X-ray production is the heating of the glass comprising the tube. About 99.8 per cent of the energy of the applied wattage is transformed into heat, and in conducting this away the glass may give up traces of gas or even melt. A strong blast of air bathing the tube is very effective in raising its capacity. The author operates a tube continuously at 5 milliamperes and about 32,000 volts.

Meters are placed in the various circuits to indicate the filament current, the milliamperage of the high-tension circuit through the tube and the primary voltage across the transformer. From this primary voltage the potential backed up by the tube may be roughly estimated.

For moderate input the Coolidge tube is self-rectifying on alternating current. Very little inverse current is noticeable until the target reaches approximately the temperature of the filament, and this condition is not reached in continuous running without disastrous results to the tube. However, in the interest of accurate voltage control across the tube, a synchronous rectifier, though not essential, is conveniently placed as shown in Fig. 1.

Built-up mica preparations have been very useful as insulators in the author's equipment. Either tubes or plates may be obtained which can be adjusted to fit the contour of housing by bending under pressure while heated.

Complete installation and operating instructions invariably accompany X-ray equipment.

For crystal analysis a few thin flat beams are required and all other rays must necessarily be stopped. A complete housing of $\frac{1}{4}$ -in. lead sheet accomplishes this very

easily. It has been stated that even comparatively weak X-rays may be injurious to the human body after very prolonged exposure—so the safest scheme is to know where all the rays are emitted and arrange to absorb them positively.

Fig. 2 shows one of the author's outfits diagrammatically, and Fig. 3 is a photograph of the set-up. The target-face is horizontal, the axis of the tube at 45 deg. as shown in Fig. 2. The beams utilized (AB) lie on the surface of a flat cone springing from the target as apex, whose elements are at about 10 or 12 deg. to the plane of the target. Even the broad focus target under these conditions presents almost a "line-source" to the slits in the housing C. All slits for defining and screening the ray should be tapered—that is, smaller toward the source—to prevent the material of slit from scattering the rays, and thus interfering with the action of the beam on the specimen D.

To filter out and stop radiations of all but a narrow range—i.e., to secure monochromatism—Hull uses 0.35 mm. thickness of zirconia. The author uses a very pure sheet rubber as a filter into which the proper amount of zirconia has been compounded. The filter (F) must be placed on the inside of the screening slit, so that the latter will confine the scattered rays derived from the fluorescence induced in the filter. Zirconia is moderately transparent to the strongest molybdenum wave-length. Its fluorescence has furthermore dominant characteristic wave length (0.0690 Ang.) longer than the two shorter molybdenum lines, so that the latter are transformed into the characteristic zirconia wave-length and emitted in all directions. The screening slits prevent this general fluorescence from reaching the film. Fig. 4 shows the effect on a pattern of pure iron of filtering

FIG. 3. ASSEMBLY OF APPARATUS FOR MAKING SIMULTANEOUS EXPOSURE

FIG. 4. SPECTROGRAM OF ALPHA IRON; WITHOUT FILTER ABOVE,
WITH ZIRCONIA FILTER BELOW

for monochromatism. As a matter of fact, the molybdenum alpha ray which is used, $0.712 \text{ \AA}$, is not strictly homogeneous, but is a mixture of two very nearly equal wave-lengths, and gives a double line with fine definition at a considerable diffraction angle. If recognized, this does not cause any ambiguity, however.

A form of screening slits is shown in Fig. 5. A wrought-iron pipe turned down and opened up supplied the material of construction. It is adjustable for width of beam, by means of the set screws shown.

An improved arrangement has been designed whereby the entire electrical equipment (tube and connections) is placed in a lead tank containing transformer oil, an arrangement which will more effectively protect the operator from accidental shock from contact with high-voltage conductors.

As will be shown, the specimen must lie at the center of a circular film. Therefore the author has built all film holders with a rigid specimen holder as an integral part. Rigid stops against which the specimen is pressed by springs keep the alignment very accurate at all times.

Two types of holders are shown in Fig. 6. The one at the left has the specimen well inside the film holder and permits use of a longer film. Also the holder is divided so that two patterns may be recorded simultaneously on one film for close comparison. The other type has an exposed and easily accessible specimen holder. Aluminum sheet 0.007 in. thick is fitted to the

¹The Angstrom unit of length (10^{-8} cm.) is a most convenient one for X-ray wave-lengths and atomic spacings.

holder in the arc of the circle; this provides a smooth resting place for the film and serves to filter out any soft rays (long wave-lengths) which may be produced by fluorescence of the sample or filter, and tends to give a more "contrasty" film. The film is conveniently placed in a black opaque paper envelope.

The author finds the duplitized film most sensitive.

A sheet of Patterson special intensifying screen is placed in the envelope on the side away from the specimen. This screen transforms much of the rays not absorbed in the film—which would otherwise be lost—into actinic light, which in turn acts upon the film to record the pattern and greatly shortens the time of exposure. Two strong rubber bands encircling the

FIG. 5. SERIES OF SCREENING SLITS

whole film holder serve to maintain a very intimate contact between film and intensifying screen—a most necessary condition.

Before considering the details of apparatus further, let us see what happens to the beam as it strikes the specimen. Fig. 7 very crudely represents the diffraction of a pencil of X-rays directed upon a conglomerate of many tiny crystal units. As we desire only to measure the angles of the several diffracted beams from the main beam, we do not need to record the whole circles. If we place a narrow film in the arc of a circle about the

FIG. 6. TWO TYPES OF SPECIMEN HOLDERS

FIG. 7. CONES OF RAYS DIFFRACTED FROM A FINE GRAINED SPECIMEN (CUBIC FACE-CENTERED SYSTEM OF CRYSTALLIZATION)

specimen as center, it will give us conic intersections with a very slight curve, and angle estimation becomes only a linear measurement along the film. A convenient radius is 114.6 mm., or 4 $\frac{3}{4}$ in. In this case each degree is 2 mm. on the film. There is such disparity in intensity between the direct beam and any of the diffracted beams that enormous halation would result on the film if some means were not employed to cut down its intensity. This is accomplished by interposing about 0.025 in. of lead. It should not exceed about $\frac{1}{2}$ in. at the most in width, lest it obliterate some of the pattern. The main beam should then register with intensity comparable to the reflected lines.

With this set-up a 24- to 36-hr. exposure will yield a film which will show black lines—such as in Fig. 4.

The mechanism of the diffraction of X-rays has been described frequently and the reader is referred to Bragg's "X-Rays and Crystal Structure"; Chapter 13, "X-Rays," by G. W. C. Kaye; and A. W. Hull's paper in *Physical Review*, vol. 10, No. 6, December, 1917.

Crystallinity requires regularity in the spacing and grouping of the atoms of the material. As a corollary to this statement, we must then be able to pass systems of uniformly spaced parallel planes, through all the

atoms, or atomic groups, in a crystal, and indeed all the data we obtain are the distances between the various parallel imaginary planes. Bragg has always considered the X-rays as being reflected from these planes, and while diffraction creates the phenomenon it is vastly clearer to consider that reflection is what actually takes place. When a system of parallel planes is in a position to reflect the X-rays, it is done precisely like the specular reflection of light, in which the angle of incidence equals the angle of reflection.

Let us consider a crystal lattice with which we are very familiar, and termed the simple cubic arrangement. Rock salt, silver chloride and calcium oxide are examples of this structure. If imaginary elementary cubes be piled regularly, at each cube corner we have an atom. Three of the possible systems of parallel planes passing through all atoms of the crystal are shown in Fig. 8. The first is composed of the cube face planes—the distance between planes will be our unit. Evidently there are three planes of this sort which are indistinguishable, corresponding to the directions of the three axes of symmetry. In the second (middle) we have passed planes through one of the six possible directions containing the diagonal edges of cubes. The spacing is $\frac{1}{2}\sqrt{2}$ times the distance between planes shown to the left, and the planes are those described by Miller as the 110 plane. At the right we have passed the 111 planes, the distance apart is $\frac{1}{3}\sqrt{3}$. We could continue passing planes through the atoms until the spacing would be very thin indeed. These spacings—it is interesting to note—would continue in a series 1, $\frac{1}{2}\sqrt{2}$, $\frac{1}{3}\sqrt{3}$, $\frac{1}{4}\sqrt{4}$, $\frac{1}{5}\sqrt{5}$, $\frac{1}{6}\sqrt{6}$, $\frac{1}{8}\sqrt{8}$, $\frac{1}{9}\sqrt{9}$, etc., with only a few omissions, notably $\frac{1}{15}\sqrt{15}$.

The condition for obtaining reflection from the atomic planes is that the wave fronts originating from all atoms encountered shall be in phase, giving in effect a nearly plane front on the reflected wave. In the diagram, Fig. 9, we have this condition existing for two wavelets also having a plane wave-front, and we may derive the formula representing the relation of wave-length λ , plane spacing d and reflection angle θ . To produce a minimum of interference when the beam is reflected from two consecutive planes, the total added length of path for the second plane must be an exact wave-length or a multiple of it. From the diagram it may be seen that this added portion of the path is $d \sin \theta$ before, and the same after reflection. Hence

$$n\lambda = 2d \sin \theta$$

where n is any integer representing the order of interference. This is the fundamental equation.

FIG. 8. THREE SYSTEMS OF PARALLEL PLANES THROUGH CUBIC ARRANGEMENT OF ATOMS

FIG. 9. REFLECTION OF TWO WAVELETS

The correct angle relations for the first three lines of a simple cubic structure of 1 Angstrom size produced by X-rays of 0.712 Ang. are shown in Fig. 10.

Obviously with a narrow monochromatic beam only one line can be reflected from one crystal at a time. But if this crystal could be rotated into every conceivable position we should obtain reflections from every plane spacing possible within the limits set by the fundamental formula. $\sin \theta$ cannot exceed 1, hence when the spacing between atomic planes is less than one-half the wave-length we obtain no reflections. Although the early investigators carefully rotated a single crystal to obtain the measure of the various possible spacings, it is much simpler to obtain many

FIG. 10. CORRECT ANGLE RELATIONS FOR FIRST THREE LINES OF SIMPLE CUBIC STRUCTURE

lines from metal simultaneously by a chaotic mixture of many tiny crystals. Such an aggregate will present crystals to the rays in almost every conceivable orientation, and like planes similarly placed in various parts of the mass will co-operate in intensifying the waves reflected.

A fine-grained metal gives a good distribution of smooth lines on the film, while a coarse grained structure is spotted and shows dashed lines, as would be expected. Some months ago the author undertook a study of this phenomenon to obtain a method for grain size determination in materials for which the ordinary method of microscopic examination is inadequate.

The deciphering of a pattern on the film as complex, say, as the one for cementite (Fe_3C) represented in Fig. 11 might well seem impossibly difficult. The method used, of course, is to build up a crystalline lattice whose distances from atom plane to atom plane are such as those indicated by the pattern. The "cut and try" method is the one forced upon the investigator in a large measure, but some circumstances ameliorate this hopeless prospect. The worker in metals finds a very few crystal habits; these are largely in the cubic system, together with a few hexagonal and tetragonal arrangements. Furthermore, Hull and Davey have

added to the convenience of interpreting films by preparing a number of diagrams which show the atomic distances for a large number of possible lattices.⁵ For instance, Fig. 12, reproduced from their paper, shows the spacings for a face-centered tetragonal crystal having all possible ratios of horizontal to vertical axis between 0.1 to 1.5. It may be noted in passing that the body-centered and face-centered cubes occur on this diagram, since a face-centered tetragonal crystal with axial ratio of 0.707 corresponds to the former and an axial ratio of 1.0 to the latter.

The scale of abscissas is logarithmic, so that if the ratios between plane spacings be figured from the exposed film and plotted on the scale at the bottom of the plot, they may be compared directly without regard to the absolute dimensions. In Fig. 12 a strip of paper bears such a series of lines derived from powdered indium, and by trial it is seen to fit well into the position shown, from which it is inferred that it crystallizes in the face-centered tetragonal system, very close to cubic but elongated 6 per cent in the direction of its principal axis. Such, in brief, is the method which allows determination of crystallinity.

It may be seen now that the preparation of the sample is of great importance. For accuracy a small thread of the material about 1 mm. in diameter is preferable, but for many determinations a flat surface of cast or powdered metal placed a few degrees to the beam is desirable. The results are nearly identical whether the surface reflections are obtained or whether the pattern

is made up of the deeper reflection from a transmitted beam. The criterion is the absorption of rays by the material. "Shooting through" is desirable for materials of low atomic weight, but specimens of high atomic weight sufficiently thin for this method are difficult to produce.

If the surface is inherently different in nature from the interior, the superficial reflection may be misleading; naturally oxide is to be avoided.

Powdered crystals should pass a 200-mesh screen;

FIG. 11. REPRESENTATION OF THE FIRST FEW LINES ON THE CEMENTITE PATTERN

some materials thus finely divided still produce spots in the film. Some materials when powdered show a great tendency toward packing into a favored orientation; for instance, graphite is a notorious offender. The author mixes such materials in heavy shellac solution and stirs up the paste, which subsequently dries without any tendency to orient itself selectively. Such tiny

⁵"Graphical Determination of Hexagonal and Tetragonal Crystal Structures From X-Ray Data."

FIG. 12. INDIUM PATTERN COMPARED WITH FACE-CENTERED TETRAGONAL PLOT

briquets are frequently strong enough to use in the same manner as solid metal would be used. As small an amount of binder should be used as will adhere the mass, for any amorphous material will produce sufficient random scattering to cause a general blackening of the film.

The difference in atomic volume between some materials cannot be discerned from the patterns

the less divergent lines resulting from the wide spacings of the heavier atoms alone. Thus with AgCl we obtain only the face-centered cubic pattern of half the atoms in the compound. The reader may satisfy himself by visualizing two interpenetrating face-centered cubic lattices. The result is a simple cubic system of half the size. Fig. 13 shows this pattern along with elemental silver, and it is apparent that the spacing of the planes in elemental silver bears a fixed relation to the planes of silver chloride. In a good film there is a faint trace of the simple cubic pattern superimposed upon the face-centered pattern of the heavier material. With salts in which the atoms are of similar atomic weight such as NaF, KCl and MgO, the simple cubic pattern is dominant and only a faint trace of the pattern of the like atoms shows.

FIG. 13. PATTERN OF METALLIC SILVER (ABOVE), COMPARED TO PATTERN OF SILVER CHLORIDE (BELOW); SHOWING EFFECT OF DIMENSIONS IN SPACE LATTICE

obtained, and indeed they may conceivably be identical. Thus tungsten and molybdenum are just sufficiently different to give patterns which with fine definition do not coincide. An austenitic manganese steel pattern is indistinguishable from the pattern of nickel. But in most cases the pattern is absolutely characteristic of one substance. Hence here is a qualitative analytical method of wide application.

The applications of the method will not be discussed in this paper, but the behavior of some types of substances will give some idea of the problems which may find a solution in crystal structure study.

In the case of compounds it so happens that very often the lighter atoms are unable to "interfere out"

Fig. 14 shows comparatively the patterns of three closely related lattices of the cubic system. It is interesting to note that in all the cubic patterns obtained the versines of the angles on the film (not the half angles) bear an integral relation to one another. This becomes more obvious when one recalls the relation $\sin^2 \theta =$

FIG. 14. PATTERNS FROM THREE CLOSELY RELATED CUBIC LATTICES

a—Simple cubic; edge = 2.55 Ang. b—Face-centered cubic; edge = 2.55 Ang. c—Simple cubic formed by two face-centered lattices of size b, the new arrangement having edge = 1.275 Ang.

FIG. 15. NICKEL PRESERVED IN ITS SOLID SOLUTIONS
a (above)—Pure nickel. *b*—40:60 nickel:chromium. *c*—30:70 nickel:iron.
d—50:50 nickel:copper.

$\frac{1}{2} (1 - \cos 2\theta)$. In the cubic system $\sin \theta$ is proportional to the square roots of certain integers, as was mentioned in a previous paragraph. Thus this function in the face-centered pattern forms the ratios 3, 4, 8, 11, 12, 16, 19, 20, 24, 27, 32, 35, 36, 40, etc.

In the case of mixtures, the method yields a film

FIG. 16. ALUMINUM (ABOVE), SILICON AND THEIR EUTECTIC

which contains the characteristic lines of both materials. For reasons which are too involved for discussion some materials give weak lines with exposures that produce strong lines with other materials. Hence in mixtures we may find a great disparity in the intensity of the two patterns, which cannot be accounted for by the proportions present. However, in the case of mixture of similarly reflecting substances, the relative intensity is a fair measure of constitution. The author has been able to secure a strong pattern from a constituent which made up only about 9 per cent of the volume of the specimen and very weak lines from considerably lesser proportions. On the other hand, one material which

FIG. 17. WHITE CAST IRON

appeared to occupy about 40 per cent of the volume yielded no visible pattern. As a method of quantitative estimation the method holds little hope.

In Fig. 15 we may see that the lattice of nickel has not been changed by the addition of 70 per cent iron, 40 per cent copper and 60 per cent chromium. It seems likely therefore, at least in the case of metals having limited solubility in the solid, that the atoms of solute simply replace up to a certain proportion of the atoms of the solvent in more or less uniform distribution without materially distorting the lattice. Presence of additional solute creates a new phase—a new crystal lattice consisting of intermetal-

lic compound or the solute element itself containing in its lattice more or less of the solvent. If the second phase is capable of existing with composition overlapping the limit of the first, we say there is complete or continuous solid solution such as Cu:Ni or Ni:Cr.

In the case of some continuous solid solution types of binary alloys, the author was able to show the presence of two crystal lattices existing simultaneously, exactly as would be expected from certain compositions and heat-treatments. Presumably at higher temperature one of the forms might entirely disappear.

Eutectic mixtures usually show coarser grain characteristics for the pattern of one of the constituents than for the other. Fig. 16 shows the eutectic of aluminum and silicon and a faint trace of the cementite is revealed in the white cast iron of Fig. 17.

Probably one of the most striking uses of the method is the determination of allotropy. The verification of

the allotropy of iron and cobalt attracted the author immediately. There is no mistaking the difference in pattern of alpha and gamma iron represented in Fig. 18.

FIG. 18. PATTERNS OF ALPHA IRON (ABOVE)
 AND GAMMA IRON

Some metals severely worked in one direction produced films in which the lines corresponding to one or more spacings are extremely weak. This is due probably to the persistence of favorably oriented grains and hence a predominance of certain spacings in the beam from a particular direction.

Judging from some preliminary tests, it seems possible that some light may be thrown

upon the matter of the unusual embrittling of certain metals observed when they are subjected to nascent hydrogen or when plated out from solution in the cold. The actual number of intermetallic compounds which exist in the copper-tin-zinc series may be verified with comparative ease by the method of study applied to the problems mentioned. This work has been begun in the spectrometers of the author's equipment.

UNNOTICED POTENTIALITIES

To one who reads critically, the incompleteness and superficial character of this account will be apparent. The possible applications of the method have been much more attractive than refinement of the process, and this fact is by no means concealed in the description. One cannot but be impressed by the potentialities of an implement of research so "fine-grained" that it reveals the mode of association of the atoms themselves. With this in mind it is perhaps not surprising that illuminating information regarding the allotropy of iron and the hardening of steel has been yielded by the spectrometer in the few months since its design and installation in the author's laboratory. At any rate this comparatively new line of attack upon problems of physical metallurgy bids fair to produce some of the next set of answers to the interminable questions "how" and "why."

Notes on Aluminum Die-Castings

BY F. A. LIVERMORE

DIE-CASTING may be defined as metal castings made by forcing molten metal under pressure in a metallic mold or die. It is necessary to keep this definition in mind to avoid confusing this process with other permanent mold-casting processes.

Only alloys of comparatively low melting point have been successfully die-cast but the finished castings are extremely accurate and free from all irregularities. Aluminum die-castings not exceeding 1 in. in any direction can be cast with an accuracy of 0.0005-in., the resultant castings possessing smooth surfaces which can be polished without intermediate machining.

Die-castings in aluminum weighing 30 to 40 lb. each are now being turned out in considerable quantities. Aluminum pistons and other parts for automobile and airplane engines have been made, which are subject to severe strain at high temperatures when the tensile strength of the metal is generally very poor. Such castings would have a strong tendency to brittleness but for the characteristic high thermal conductivity as compared with iron and steel.

SUITABLE DIES AND DIE-CASTING ALLOYS

In the first attempts to die-cast aluminum the problem of obtaining a suitable die material presented serious difficulties. This problem, however, has been solved by the use of various alloy steels. The proper gating and venting of the dies are also problems that arise daily, and on the solution of these problems depends largely the success or failure of the operation. Chromium-vanadium steel is generally used, although in some cases cast-iron dies are used for castings of simple design.

Just what constitutes a good die-casting alloy is a subject of unusual interest; a few of the important requirements outside of the usual physical properties demanded of alloys are:

Solvent Action. The solvent action of the alloy on the iron containing pot and the die must not be too great. Overheated aluminum dissolves iron very rapidly. Analyses of aluminum die-castings on the market will show an iron content of from 1 to 3 per cent. Although the presence of iron in aluminum presents no serious objections in sand-cast alloys, the absorption of the above 3 per cent iron considerably raises the melting point and the alloy becomes viscous and unsuitable for making die-castings.

Elongation. The elongation of the metal is of vital importance in determining the die-casting properties of an alloy. Not only is it desirable to know the elongation of an alloy when cold, but it is of greater importance to determine the elongation at various temperatures varying from the melting point of the alloy down to normal temperatures. The reason for this becomes obvious when the physical phenomena of the die-casting process are considered. Let us assume that a ring 12 in. in diameter is to be die-cast in a metallic mold around a metallic core. When the molten metal comes in contact with the mold it changes state, solidifies, which is accompanied by a shrinkage in volume. The metallic core, not being compressible, retains its size and form, so that the die-casting is subject to a "stretching" action and if the ductility of the alloy at this temperature is not high enough to withstand this strain, the casting will crack.

It is well known that the addition of a "hardener," say copper, reduces the elongation of aluminum. An aluminum alloy containing 12 per cent of copper will show less elongation than an alloy containing only 6 per cent of copper when testing it at normal temperatures. Nevertheless the 12 per cent copper alloy has a greater elongation at high temperatures than the 6 per cent and consequently the 12 per cent alloy is better able to withstand the casting stresses to which it is subject in the die-casting process.

The zinc-base alloys are not suitable for casting in metal molds (especially if commercial spelter is used), for they absorb iron from the molds and show a striking tendency to hot-shortness. An alloy of 92 per cent aluminum, 7 per cent copper and 1 per cent manganese gives very good results for die-casting under pressure, since this alloy sets forth a practical compromise between the antagonistic requirements of low melting point, high tensile strength and ductibility at temperatures just below the point of solidification.

DIE-CASTING

The metal to be die-cast is melted in the furnace crucible and the temperature of the furnace regulated by means of a pyrometric installation, so that the alloy is kept at a uniform temperature about 10 deg. C. above the melting point of the alloy.

The assembled dies are heated to about 500 deg. F. (260 deg. C.) and fixed over the nozzle of the machine. The sprue-cutting bar is released back, thus opening the nozzle, and the metal molten is forced into the dies by air pressure.

When the mold is full the sprue-cutting bar is brought to position, thereby cutting off the supply of metal. The die is opened, the casting removed, the die reassembled and the operations are repeated.

The dies should be lubricated now and then, this facilitating the removal of the casting and protecting the die surfaces; a mixture of lard-oil, beeswax and graphite is used for this purpose.

Air Bubble Viscosimeter

BY VICTOR R. ABRAMS,* JOSEPH T. KAVANAGH†
AND CHARLES H. OSMOND§

THE principle that a restricted air bubble, confined within a tube of definite small diameter, will move upward by influence of gravity through a mass of oil, the action being duplicate under identical conditions, and that this rate is a function of the viscosity of the oil, has been applied in the construction of a compact, portable type of viscosimeter.

This viscosimeter, named by the authors the "Atreco" viscosimeter, requires only a very small quantity of oil for operation, is capable of rapid manipulation and has an experimental error no greater than that obtained with the Saybolt Universal viscosimeter.

The instrument consists of a piece of glass precision tubing, 21 cm. long with an internal diameter of 5.2 mm. One end of the tube is sealed by blowing thereon a bulb of spherical shape about 8.5 mm. in internal diameter. The opposite end is ground with a slight taper and a cap is made to fit thereon. By grinding the cap on the end of the tube an airtight contact is made. Previous to this grinding, a small hole is made through the side of the cap for overflow when filling with oil. A "V" shaped groove is cut in the cap end of the tube to act as a trough, for outflow in conjunction with the small hole in the cap. By grinding off the end of the tube, air space in the cap can be modified, until proper size of bubble is obtained. It has been found that an air chamber which will produce a bubble 17 mm. long $\pm$ 2 mm. is very satisfactory. Two lines are etched or engraved around the external circumference of the tube, about 10 cm. apart, with the included space at the middle section of the length of the completed tube.

The tube, after being thoroughly cleaned and dried, is filled with the oil to be tested. The cap is adjusted so that the hole in its wall is over the overflow trough in the tube. The tube is now immersed in a water bath at the desired temperature of the test, allowing the cap to be above the water level. The oil will expand and escape through the overflow trough and hole. When no further expansion is noted, the cap is turned, thus sealing the tube with its contents of oil and air. The tube is then placed within its holder (see illustration) and the entire instrument is placed in the water bath.

ATRECO VISCOSIMETER

This bath should be in the form of a glass cylinder, so that the instrument is plainly visible when looking through its walls. The water bath should be maintained at the desired temperature of the test.

Invert the tube, thus allowing the bubble to rise. This first run is not recorded. As rapidly as possible make five determinations by inversion of the tube after each one, making sure that the bubble has traversed the entire length of the tube. The determination is made by observation of the number of seconds and fractions thereof that elapse between the passing of the bubble from one line on the tube to the second line, care being taken that the notation is always made at the same point of the bubble. The average of these five determinations, when multiplied by the factor governing the calibration of the tube, will give the Saybolt Universal value (seconds) of the oil at the desired temperature. The bath must be maintained at this temperature for accurate determinations.

CALIBRATION

The Atreco viscosimeter is calibrated in the following manner: A duly certified standard Universal Saybolt viscosimeter is used to obtain the viscosities of a group of oils ranging from 80 to 475 seconds Saybolt at 100 deg. F. Check runs are made of each oil until a Saybolt Universal value is obtained that can be considered accurate. Care must be taken in standardizing oils on the Saybolt instrument not to re-run the same sample, as it has been found that if the same oil is re-run a number of times, the values obtained may vary considerably. The retained samples are then tightly sealed until ready for use in standardizing the Atreco viscosimeter. The tube of the Atreco viscosimeter is now filled and the oil expanded at a temperature of 100 deg. F., as noted in method of operation, the surplus oil being forced out through the opening in the cap. The cap is adjusted to seal the tube and the tube is placed in the metal holder or container for convenient and accurate form of suspension; the instrument is immersed in a water bath kept at 100.25 deg. F. and allowed to remain a few minutes for the purpose of stabilizing temperature. The instrument is now inverted, thus causing the bubble to rise. The first run is not recorded, being made to allow the oil to wet the internal wall of the tube thoroughly. Five runs are now made (by inversion of the instrument), measuring the exact time required for the same point of the air bubble to travel from one mark to the other. The exact average of the five runs in seconds is taken as the true time. This average result divided into the Saybolt Universal viscosity gives the factor of the instrument.

For accuracy, it is advisable to take four oils with respective viscosities of 90, 130, 230 and 475 Saybolt seconds at 100 deg. F. and obtain the resultant factors. It will be noted that the factors so obtained will agree to within a few hundredths, a variation liable to experimental error. These facts apply to tubes within the dimension limits given and will show deviations as hereafter noted when other size tubes are used.

This method of calibration has proved thoroughly practical and results obtained are within the range of accuracy claimed for the instrument. The use of distilled water as a calibrating liquid is not practicable.

As shown in Table II the presence of adulterants produces no effect on the usefulness or accuracy of the instrument. It will be noted that results show deviations of approximately 0.5 per cent. and it is believed

*Technical engineer, Atlantic Refining Co.

†Physicist, Atlantic Refining Co.

§Physical chemist, Atlantic Refining Co.

that by using ordinary care and technique, variations should not be more than 1 per cent of the Saybolt Universal outflow time on oils of viscosity not less than 80 seconds Saybolt Universal.

It was suggested by J. M. Maris that a pocket type viscosimeter might be developed by the application of Stokes' law, which relates to the movement of an unrestrained sphere in a mass of fluid. This was found impracticable after study, confirming results obtained by Prof. Mills in the study of measurement of viscosity by use of an air bubble. Thus the restricted bubble type of instrument was developed.

LIMITATION OF THE INTERNAL DIAMETER OF THE TUBING

The first point of consideration, after experimentation had demonstrated that a restricted bubble could be used for definite determinations, was the internal

* Length distance between etched lines.

diameter of the tubing. Precision tubing was found essential for accurate results. Tubing with an internal diameter of from 3.0 mm. to 7.0 mm. was tried, but it was found necessary to limit the internal diameter to 5.0-5.6 mm. in order to operate practically with both high and low viscosity oils.

The final procedure was the selection of a proper sized tube to give a definite relative value to the Saybolt viscosity. Many trials were made with tubes of the following internal diameters: 5.0, 5.1, 5.2, 5.3, 5.4, 5.5 and 5.6 mm., using the same length of bubble and under as nearly identical conditions as possible.

Results showed that the tubes with an internal diameter of 5.0 and 5.1 mm. had factors which decreased as the viscosity increased; tubes with an internal diameter of 5.4, 5.5 and 5.6 mm. had factors which increased as the viscosity increased, but tubes with an internal diameter of 5.2 and 5.3 mm. had factors which produced results differing by not more than the experimental error.

The limits for the internal diameter of the tube were therefore determined to be 5.2 and 5.3 mm. A tube of internal diameter within these limits gives variations which compare with Saybolt variations for the same oil, thus yielding values which may be converted into Saybolt seconds by use of a constant factor for each tube. The time of operation of a tube of this diameter is neither too short for accuracy nor too long for convenience.

The middle section of the glass tube was chosen for observation to eliminate possible end effects and to allow sufficient time for the bubble to assume a constant condition.

The end of the tube was blown with enlargement,

corresponding to the cap end, in order to retard the bubble and thus permit sufficient time for proper observation.

Constant volume of the bubble is obtained by provision of the overflow at cap end of the tube and through the small hole in the cap. This constant volume was considered necessary for proper operation.

Observation of a tube in operation shows that the passage of the bubble upward is made possible by the displacement downward of a volume of oil equal to the cross-sectional area of the bubble times the distance swept through. This displacement takes place as an annular flowing film surrounding the bubble and produces a capillary corresponding to that in a short tube viscosimeter. As far as can be observed this capillary film is of uniform thickness for any definite condition when the tube is in a vertical position, but its uniformity is rapidly destroyed and the movement of the bubble accelerated by any small variation from the vertical.

Table I shows the results obtained in the calibration of four separate Atreco viscosimeter tubes for their Saybolt factor. Table II shows typical results obtained, using four separate instruments and a number of oils covering a Saybolt viscosity range of 90 to 476 at 100 deg. F.; the error in seconds between the actual determination and the factor determination; the absence of any effect upon the results when mineral oils containing adulterants, such as may be used in compounded oils, re tested.

USES OF THE INSTRUMENT

This instrument is applicable in a number of cases where small samples of oil only are obtainable. The average tube requires for operation about 4 c.c. of oil.

Another use for this instrument is the obtaining of the viscosity-temperature curve of an oil in a relative short time as compared with the usual method. As the results of the Redwood, Engler and Barbey instruments are all convertible to the Saybolt values, it can readily

be seen that a conversion factor may be determined to give results comparable to any of these instruments.

There is also the possibility of the use of the Atreco instrument in the field, or where the laboratory methods are not possible or practical. In this case the bath would be eliminated and the reading made at air temperature. The viscosity as obtained at this temperature might be converted into viscosity at 100 deg. F. and at least an approximate value obtained that would yield sufficient information until a more accurate determination could be made.

Laboratories of the Atlantic Refining Co.,
Philadelphia, Pa.

Resistance Type Electric Furnace Tested for Steel Melting

THE value of the arc furnace of the Heroult type in the production of the highest grades of steel has become so well known that it is now generally accepted that steel of crucible quality can be made without difficulty in these furnaces, and already a large part of the highest quality of steel is so made.

However, it has been found difficult to replace all the crucible pots on account of the difficulty in pouring ingots from a ladle without some sculling. One reason why they are still used for some high-grade steels is the convenience of the small size pots for special mixtures, allowing small heats to be poured; and the fact, as

FIG. 1. BAILY FURNACE AND CASTING TABLE USED FOR MELTING STEEL

mentioned above, that the existing type of arc furnace in service requires a ladle in order to pour the charge into the molds, which gives a marked difference in the teeming temperature of the metal between the first ingot poured out of the ladle and the last ingot, as well as the loss of metal in the form of scull in the ladle.

In order to obviate these difficulties in the existing type of electric unit, the Electric Furnace Co. has recently carried out experiments in its laboratory at Salem, using its resistance type furnace, with the view to adapting it for that portion of crucible quality steel now handled in pots. The company's 1-ton furnace is built in the nose-tilting type, alongside a casting table on which molds are mounted (Fig. 1), so that the metal can be poured directly to the molds without any ladle at all, which is the practice where these furnaces are used in brass-rolling mills. This gives uniform temperature throughout the pour, eliminates the ladle entirely and makes the pouring condition analogous to that of crucible practice.

Tests showed that there was no difficulty in keeping steel of as low carbon content as 0.05 per cent at good pouring temperature. The maximum temperature obtained on the hearth was 1,850 deg. C.

The test sheets (Table I) show not only the temperature obtained but the melting rate as well. These tests and subsequent tests indicated that crucible quality steel can be made and poured in small furnaces of this type with a current consumption of not to exceed 1,200 kw.-hr. per ton, which, while much higher than the figures obtained in arc practice, nevertheless will produce steel much more economically than by crucible practice.

	4 p.m.	980	65	64	3,090	202,009	5 lb. roll scale charged 4:40, poured at 4:52

The furnace used for the steel test was a standard 7-ft. diameter, brass-melting furnace, having a hearth capacity of 2,000 lb.; and in addition to the 4½-in. fire-brick lining used in brass melting, a 9-in. magnesite brick lining was placed directly inside. The roof was made of 9-in. silica soap shapes, and was not insulated.

Synopsis of Recent Chemical & Metallurgical Literature

Elastic Properties of Steel After Overstrain.—Research Department Report 45, issued by the Woolwich Arsenal, England, under authorship of R. H. Greaves, is abstracted in the *Iron and Coal Trades Review*, July 15, 1921. Tables I and II give an outline of the main results of the study. Samples 3 and 5 were overstrained in compression, then tested in tension, and it was found that the elastic limit had fallen almost to zero. A marked reduction in the virgin

TABLE I. ANALYSES OF MATERIALS TESTED

Mark	Material	C	Si	Mn	S	P	Ni	Cr
1	1-in. bar.....	0.34						
2	Normalized proof shot...	0.50	0.16	0.70	0.048	0.056		
3	2½-in. bar.....	0.77	0.12	0.34	0.03	0.027		
4	12-in. howitzer jacket*...	0.34	0.10	0.64	0.031	0.025	3.65	
5	Cast 12-in. H.E. shell (heat-treated).....	0.32	0.24	0.49	0.031	0.024	2.12	1.45
6	1-in. bar, air-hardened and tempered.....	0.30	0.16	0.26	0.017	0.028	1.95	5.23

* Tested transversely.

elastic limit in tension occurred even after low-temperature annealing. Cold-drawn gun wire is also known to be more reluctant to recover its original elastic limit than the same normalized steel after less severe overstrain.

It is evident that, in general, recovery of the virgin elastic limit after overstrain in tension proceeds slowly at atmospheric temperature (in some cases very slowly) and more rapidly with increased temperature. A high-temperature softening anneal, of course, must be avoided. Time for recovery varies directly with the degree of overstrain. Rate of recovery also depends upon composition and heat-treatment (being slow for hard steels).

Interpreted in terms of the amorphous theory, the author points out that amorphous material generated at crystal-line slip planes is initially in a mobile condition, and on reloading allows the steel to acquire a permanent set at

comparatively low loads—hence the lowered elastic limit. Unloading is accompanied by a return flow of the viscous material, resulting in a greater contraction than corresponds to the elastic contraction of the crystalline material, a backward creep which sometimes continues after all load is removed. These experiments indicate a considerable

TABLE II. EFFECT OF REPEATED TESTS ON ELASTIC LIMIT

Mark	First Overstrain	Complete Recovery of Elastic Limit	Effect on Young's Modulus	Partial Recovery of Elastic Limit
(1)	1.5 per cent stretch	10 min. at 100 deg. C.	Restored.....	
(1)	6.5 per cent stretch	40 min. at 100 deg. C.	Small decrease	
(2)	Moderate stretch..	12 hr. at 100 deg. C....	Restored.....	32 mos. at atmosphere
(2)	Further and repeated stretches..	1 hr. at 195 deg. C....	Restored.....	
(4)	2 per cent stretch...	1 hr. at 200 deg. C....		33 mos. at atmosphere
(5)	Moderate stretch..	31 mos. at atmosphere. 2 hr. at 100 deg. C.... 1 hr. at 195 deg. C....	See note 1....	
(6)	Moderate stretch..	See note 2.....	Restored.....	1 hr. at 350 deg. C.

NOTE 1.—Modulus, originally low, was raised after recovery from overstrain. Successive loadings caused progressive approach to the proportional line up to the load applied, the successive permanent sets tending toward zero. The proportionality reached by loading and unloading in this way was quite fictitious, as an indication of the elasticity of the material, and corresponded to a much reduced modulus.

NOTE 2.—Proportional limit very difficult to determine, but recovery not complete after 1 hr. at 350 deg. C.

variation in viscosity of this yielding material. The amorphous material "sets" or becomes rigid in some manner after a certain time, depending on the temperature. It is still thought to be non-crystalline, but in a hard, non-yielding or vitreous condition, and as such prevents further slip on the same gliding planes and stiffens the mass of the metal.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Process of Producing Formaldehyde.—The commercial production of formaldehyde from methanol by catalytic oxidation requires relatively pure raw materials and temperatures of 400 deg. C. or higher. It has been found that by using vanadium pentoxide as the catalyst it is possible to produce better yields of formaldehyde from the methanol, that the catalyst is not affected by poisons such as acetone and water, which are the common impurities of methanol, that it reacts at a sufficiently low temperature to be below the decomposition point of formaldehyde and that a large excess of air is beneficial to the reaction. A temperature as low as 225 deg. C. can be used and it is claimed that methanol containing as much as 5 per cent of acetone will give satisfactory yields. (1,383,059; George C. Bailey and Augustus E. Craver, assignors to The Barrett Co. of New Jersey; June 28, 1921.)

Manufacture of Acetaldehyde.—Howard W. Matheson, of Shawinigan Falls, Que., Canada, has patented an improved process for producing acetaldehyde on a continuous, commercial scale and without the formation of resins and condensation products of the aldehyde. It is also claimed that with the new process there is a saving in the amount of catalyst required. The process consists of passing commercial acetylene through dilute sulphuric acid, containing not more than 6 per cent of acid and a small amount of a mercury salt. The gas is passed through in greater excess than is required to form the acetaldehyde. The reaction is carried out at comparatively low temperature and pressure, thus avoiding the danger and corrosive action common to the older process. The mercury salt is very slowly reduced and does not remain in suspension in the liquid, but settles to the bottom of the reaction vessel,

where it can be easily drawn off. The large excess of acetylene carries the aldehyde out of the reaction liquid as soon as it is formed, so that it does not remain in contact with the acid a sufficient length of time, nor is it subjected to a sufficiently high temperature to form aldehyde resin or crotonaldehyde or other undesirable products. The yield of aldehyde is large, equaling almost the theoretical amount, and is produced very rapidly. (1,384,842; July 19, 1921.)

Acid-Resisting Alloy.—Colin G. Fink, of Yonkers, N. Y., assignor to Chile Exploration Co., of New York, has been granted a patent for an alloy to be used for withstanding the corrosive action of mixtures of sulphuric, nitric and hydrochloric acids such as are sometimes encountered in the acid liquors in the electrodeposition of copper. The alloy he describes contains lead, tin and thallium. The lead may, if desired, contain some hardening agent such as barium, which may be present in amounts up to 3 per cent. A typical example of this type of alloy had the following composition: lead, 70 per cent; tin, 20 per cent, and thallium, 10 per cent. The thallium content may be varied, however, from 3 to 65 per cent and as much as 25 per cent of tin may be used. (1,384,056; July 12, 1921.)

Halogenating Hydrocarbons.—If toluene or its homologues are chlorinated or brominated in the vapor stage, at the temperature of the boiling hydrocarbon, it is necessary that the reaction be carried out in strong light and in the presence of a catalyst such as sulphur or phosphorus. Furthermore there is often a loss of the hydrocarbon carried away in the acid gas evolved, and this gas is extremely corrosive to equipment. There is also a loss caused by the formation of nuclear halogenated products. In a recently patented process the halogen is introduced into the hydrocarbon while the latter holds in suspension an alkali-metal carbonate. It is claimed that the reaction is more rapid than could otherwise be effected at low temperatures and in the absence of light and in the presence of iron or other substances which act as catalysts for the nuclear halogenation. The corrosive action is minimized. The process is particularly applicable for producing such compounds as benzyl chloride, benzal chloride and benzotrichloride, with the production of but relatively small amounts of nuclear chlorinated products such as chlor-toluene. (1,384,909; Chauncy C. Loomis, assignor to Semet-Solvay Co., of Solvay, N. Y.; July 19, 1921.)

Production of Anhydrous Antimony Trichloride.—A continuous process of making antimony trichloride, which has recently been patented by Oliver C. Ralston, of Niagara Falls, N. Y., consists of passing chlorine gas through crushed antimony metal submerged beneath a bath of molten anhydrous antimony trichloride. The chlorine is supplied at a rate sufficient to maintain the bath in a molten state due to the exothermic reaction between the antimony and the chlorine. The trichloride is withdrawn from the reaction chamber in either liquid or vapor phase and subjected to subsequent distillation for refining purposes. Because of the constant presence of an excess of antimony metal, a product free from the objectionable antimony pentachloride is obtained. (1,384,918; assigned to Hooker Electrochemical Co., of New York, N. Y.; July 19, 1921.)

Canadian Patent

Leading-in Wire or Platinum Substitute.—This wire is composed of a core of a low expansion metal or alloy and an outer sheath or sleeve of copper whose coefficient of expansion is decidedly above that of glass. The resultant expansion coefficient of this compound wire is substantially the same as that of glass. One advantage of using copper as the sheath metal, besides its high electrical conductivity, is the great affinity of the copper oxide for glass in a semi-molten condition. That is to say, the copper will cement itself to the glass "hermetically" at the ordinary temperatures used in sealing-in operation. The wire is suitable for incandescent lamps, mercury arc rectifiers, etc. (Can. Pat. 212,365. Colin G. Fink, assignor to Canadian General Electric Co., Ltd., Toronto. July 5, 1921, Cf. British Pat. 23,775, 1912.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Pickling Metals.—A bath for removing scale from iron or steel articles contains ferrous sulphate and sulphuric acid. To accelerate the action, hydrochloric or nitric acid, or both, may be introduced. As an example, the solution contains 38 lb. of ferrous sulphate dissolved in 300 gal. of water and 112 lb. of sulphuric acid (sp.gr. 1.84). In addition, 16 lb. of nitric acid or 20 lb. of hydrochloric acid with 12 lb. of nitric acid may be added to the solution. (Br. Pat. 163,868. Rustproofing Syndicate, Ltd., Westminster, and T. F. Newman, London; July 20, 1921.)

Glycerine.—Glycerine is produced by fermenting sugar solutions containing a mixture of about equal weights of alkali bisulphite and sulphite. The mixed sulphites may be added in successive small quantities to a proportion corresponding to the percentage of glycerine desired, the proportion of acetaldehyde and alcohol being greater the less the proportion of sulphites; and the liquid may be maintained approximately neutral by successive additions of alkali bisulphite solution or by increasing the proportion of bisulphite in the additions of the mixed sulphites. In an example in which the maximum glycerine yield was required, 311 gal. of a solution of crude cane sugar equivalent to 788 lb. glucose was fermented by 40 lb. of yeast at a temperature of 25-37 deg. C. for nine days, and during the first five days 176 gal. of mixed sodium sulphite and bisulphite solution equivalent to 545 lb. Na_2SO_3 was added in doses first of 40 lb. and then of 30 lb. mixed salts in 16 gal. of water. In this way, 336 lb. glycerine, 172.2 lb. acetaldehyde, and 37.4 lb. alcohol were produced. (Br. Pat. 164,034. A. T. Cocking, Sutton, Coldfield, and C. H. Lilly, Birmingham; July 20, 1921.)

Distilling Petroleum Oils, Distillates and Tars.—In distilling petroleum oils, distillates and tars, the oil is forced by a pump through preheating tubes *P* in the condensers *N* and through a tube *A* heated by an electric coil and is admitted through a valve *C* into an evaporator *D* heated by a surrounding electric coil or by other means. The liquid is distributed by funnels *H* on to a series of inclined plates *E*.

The vapors are withdrawn by a pump, which maintains a reduced pressure in the evaporator, through a series of condensers *N* maintained at different temperatures by the pipes *P* through which the oil supply flows in series. The residual liquid from the evaporator *D* passes to a vessel *L* from which it is forced through a similar heater *R* and evaporator *S*, in which it is treated with air to yield asphalt. Vapors evolved in the evaporator *S* are withdrawn through a series of condensers *X* cooled by passage of crude oil through tubes contained within them. Steam may be admitted to the evaporator through a valve *M*. Temperature-regulators *P*, *K* are fitted to the heater *A* and evaporator *D*. In a modified apparatus, the heaters and evaporators are heated by gas or oil fuel burners, the residue from the first evaporator is passed through the cooling

coils of the condensers connected to the asphalt chamber, and is passed through an intermediate heater and evaporator before being treated to form asphalt. Cracking of the oils may be obtained by heating them above 400 deg. C. (Br. Pat. 163,363. V. C. Illing and J. Kelly, both of London; July 13, 1921.)

Electric Furnace.—A furnace of the type in which heating is effected by the combined use of arcs and resistances is provided with a floor on one or both sides of the heating zone on which a number of objects may be placed for preheating or other purposes. The arcs 5 extend between a number of vertical electrodes 3 and a bed 1 of granulated coke, graphite or the like in a trough 2 of refractory materials provided with a contact member 12. The electrodes may be arranged for direct, single-phase, two-phase or

three-phase current. Blocks 6 of carborundum or the like protect the walls of the furnace at the ends of the bed 1. A slightly inclined floor 7 extends on each side of the bed and is adapted to receive articles to be heated such as ingots 8 through door openings 9. Other openings 10 in the side walls permit the articles treated being moved relatively to the heating zone. Coils, strips or rods 11 are provided laterally of the heating zone to preheat the articles in the furnace. A trough or hearth with a taphole is provided close to the heating zone. The heat may be controlled by lengthening the arcs, disconnecting one or more electrodes or varying the voltage which is applied. (Br. Pat. 164,019; not yet accepted. I. Rennerfelt, Djursholm, Sweden; July 20, 1921.)

Reduction of Iron Ores.—Iron ore in finely grained condition is heated directly up to 1,100 deg. C. or higher—for example in a rotary kiln—and then transferred to a reduction furnace indirectly heated. Fluxes may be added before preheating or may be separately heated and mixed in the reduction furnace, to which is also added carbon or coal as is required for complete reduction of the ore. The temperature is maintained above 1,000 deg. C. but below the melting point of iron. The solid, sintered mass of iron formed is discharged, without admission of air, into another furnace, where it is melted and slag removed; the iron may be further purified and carbonized in another smelting furnace. A part of the gases liberated in the reduction furnace and consisting of carbon monoxide (and hydrogen and hydrocarbons if the fuel is coal) is burned in the heating channels of the reduction furnace, a second part is used for heating the smelting furnace, and a third part may be used for preheating the ore and fluxes by direct contact with the combustion products. (Br. Pat. 163,561. S. J. Vermaes, Delft, and Syndicaat "Electro-Staal." (The Hague, Holland; July 13, 1921.)

Removal of Dissolved Oxygen From Water.—In the removal of dissolved oxygen from water by filtration through iron filings or turnings, the layer of rust on the latter which retards complete oxidation of the filtering medium is reduced by allowing the iron and the rust to react upon each other to give ferrous hydrate. When no longer capable of rapidly absorbing oxygen, a portion of the filter bed is kept full of water until the medium becomes active again. The ferric oxide finally produced is removed from the filter by means of a current of water or steam or by stirring by mechanical means. Iron or steel filings or turnings containing from 0.5 to 6 per cent of manganese are used as the filtering medium. The manganese, acting as a catalyst, hastens the fixation of the oxygen. (Br. Pat. 164,711 and 164,712; not yet accepted. P. Kestner, Boulogne, France; Aug. 4, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Chicago Section, A.C.S., Holds First Fall Meeting

The Chicago Section of the American Chemical Society held its first monthly meeting of the winter season at the City Club on Sept. 23. The paper of the evening was presented by Charles H. MacDowell, president of the Armour Fertilizer Works, and dealt with science and the coming agriculture. In treating the broad subject of conservation of national fertility in the United States the speaker showed the definite research problems ahead of the chemist. The paper will be dealt with more fully in a subsequent issue of CHEMICAL & METALLURGICAL ENGINEERING.

The Chicago Section is growing so large it has become necessary to split into divisions similar to the organization of the semi-annual national conventions. After the discussion on the principal paper of the evening was closed, the members split into two divisions, analytical and synthetic. The discussion on definite subjects was led by able speakers in each division and many members participated. Arrangements have been made for four divisional meetings at the next monthly assembly.

American Gas Association to Meet in Chicago

Although the final program of the American Gas Association's annual convention in Chicago, Nov. 7 to 12, has not been completed, the following papers are announced:

"Why Should Gas Companies Sell Their Tar to Distillers Instead of Working It Themselves?" R. P. Perry.

"Report of Committee on Disposal of Waste From Gas Plants," F. W. Sperr, Jr.

"Report of Purification Committee," A. C. Fieldner.

"Selected and Annotated Bibliography on Gas Purification," A. R. Powell and K. C. Walker.

"The Seaboard Liquid Process of Gas Purification," F. W. Sperr, Jr.

"Effect of Moisture on Activity and Capacity of Oxides for Gas Purification," W. A. Dunkley.

"What Goes On in a Water Gas Machine?" M. E. Benesh.

"Some Experiments With the Mixing of Different Gravity Gases in Holders," H. E. Bates.

"Utilization of Compressed Air in Clearing Gas Piping," J. T. Griffin.

New Oil Companies

During the month of August, new oil companies were organized with an aggregate capitalization of \$141,544,000, including all concerns with an indicated capital of \$50,000 or over. For the first time in the present year the total exceeds that of the corresponding month of a year ago; in August, 1920, the indicated investment of new companies was \$118,370,000. An aggregate of 72 companies was formed in the 1921 August period, as against a total of 69 in July, and 103 in August, 1920. For the first eight months of the present year the showing represents 686 new companies organized in this line, with a total capitalization of \$992,601,600; in the same period of 1920, 2,136 new companies were formed with an aggregate indicated capital of \$1,777,876,000.

Sweden Lifts Export Embargo on Fertilizers

The Swedish Government announces that beginning Oct. 1 the export embargo on raw phosphate and other fertilizers was lifted.

Explosion in German Saltpeter Works

An explosion occurred Sept. 23 in the saltpeter works at Kleinlaufenberg, near Karlsruhe, Germany. Several men were killed and the material damage was considerable.

Lehigh Chemical Society Meets

The first meeting of the 1921-22 season of the Lehigh Valley Section of the American Chemical Society was held in the lecture room of the chemical laboratory, Lehigh University, Bethlehem, Pa., on Wednesday evening, Sept. 28. The meeting was preceded by a dinner at 6:30 at the Bethlehem Club.

The evening was given over to a program devoted to a "Symposium on Engineering Education," with nine or ten speakers dealing with different phases of the subject, each followed by a short general discussion. Each speaker devoted about 5 minutes to his topic. The program was:

General talk, Dr. Edward Hart; "Education for Research," Dr. H. M. Ullman; "Preparatory Education," Prof. A. A. Diefenderfer; "Resume of Educational Talks, New York Meeting," Dr. E. C. Bingham; "Culture Studies for the Engineer," Prof. A. C. S. Fasig; "The College Man and Business," J. T. Baker; "The Self-Made Man," Dr. Joseph W. Richards; "Relation of the College to Industry," Prof. D. S. Chamberlain; "Preparation for Leadership," F. G. Breyer.

Gas Used Successfully Against Old Alabama

The Chemical Warfare Service is more than pleased with the showing made with gas and phosphorus bombs dropped from airplanes on the old battleship Alabama. Even without the ventilation system being in operation, it was shown that the tear gas from the bombs dropped on the ship had penetrated throughout the vessel. As a matter of fact, the whole vicinity was so heavy with tear gas that it was four hours before the boat could be boarded without masks. Even as it was, members of the observing party had frequent use for their handkerchiefs for many hours afterward. The experiment demonstrated clearly that had poison gas been used, instead of tear gas, the entire personnel of any ship would have been compelled to resort to gas masks until the ship could have been cleared of the poison, with the resulting confusion and distraction of attention from offensive duties.

Four 100-lb. phosphorus bombs struck the ship. Three hit the decks and one fell in a fighting top. The resulting spectacle is described as stupendous. The ship was quickly enveloped in smoke and flames. Burning phosphorus was sprayed over the entire ship from the bomb which lodged in the fighting top. The effect in action would have been to blind the ship completely so that it would have been unable to single out targets or to operate its anti-aircraft equipment. Had the Alabama been a hostile ship, it is certain that the phosphorus bombs would have caused a large number of casualties among those on deck.

Demonstrations also were made of flares and signals prepared by the Chemical Warfare Service for airplane use.

Civil Service Examinations

The United States Civil Service Commission announces competitive examinations for the positions noted below on Nov. 2, 1921. Vacancies at the United States Naval Academy, Annapolis, Md., at \$4.80 to \$5.04 per diem, and in positions requiring similar qualifications will be filled from these examinations.

Chemical Laboratorian (Analytical).—The duties of the appointee will be to assist in the physical and chemical laboratories, prepare solutions, set up chemical and physical apparatus, make repairs, and conduct experimental work.

Chemical Laboratorian (Metallurgical).—The duties of the appointee will include physical tests, heat treatment, and metallographic examination of metals; determination of transformation temperatures; calibration of instruments, such as pyrometers; calculation and plotting of results of tests; making sketches and drawings of apparatus.

Rubber Mills at Trenton Operating at Capacity

The different rubber mills at Trenton, N. J., have now practically all resumed operations, including those devoted to the manufacture of automobile tires and tubes and mechanical rubber goods. A survey of the plants shows the following situation:

The Bergougnan Rubber Corp., Whitehead Road, with plant devoted to tire and tube production, is giving employment to about 250 operatives, with schedule including night shift. It is expected to add additional employees to the working force at an early date.

The Ajax Rubber Co., Breunig Ave., is maintaining capacity manufacture for automobile tires and tubes. The plant is running under a 24-hour schedule, six days a week, with current production totaling about 6,000 tires in this time.

The Hamilton Rubber Manufacturing Co., Mead and Prince Sts., manufacturer of mechanical rubber goods and automobile tires, is operating on a basis of from 60 to 75 per cent of maximum capacity.

The Thermoid Rubber Co., Whitehead Road, manufacturer of automobile tires and mechanical rubber goods, is running on a basis of about 70 per cent of normal, with the bulk of production devoted to tires. It is said that other departments of the plant are showing improved conditions, including those devoted to the manufacture of belting, brake lining and hose.

The Empire Tire Co., Mulberry and North Clinton Sts., is operating at a capacity of from 60 to 75 per cent of normal.

Improved Conditions in the Glass Industry

The general improvement in conditions in the glass-manufacturing industry during the past few weeks is leading to the resumption of operations by different plants in this line in all parts of the glass-making sections of the country. Recent plant openings are:

The Jeanette Glass Co., Jeanette, Pa., has started up with two tanks in operation, to develop a capacity of about 90 per cent of normal. Approximately 900 employees have been taken on.

The Central Glass Co., Wheeling, W. Va., has resumed partial production, following a suspension of operations since July 1. About 150 men will be employed at present, and this number is expected to be increased soon.

The Bridgeport Lamp Chimney Co., Bridgeport, near Clarksburg, W. Va., has reopened its plant, giving employment to about 150 men.

After a shut-down of several months, the Gill Brothers Co., Steubenville, Ohio, has resumed manufacture at its local Aeme plant, with one furnace in operation. It is planned to increase the rate of output in the near future.

The Bellaire Bottle Co., Bellaire, Ohio, has reopened its plant on a basis of three days a week until further notice.

The Standard Glass Works, Marion, Ind., has resumed operations at its local plant, following a shut-down of several weeks. The Canton Glass Co., in this same city, is also operating its plant under good capacity, and reports a marked increase in orders.

Waste Alundum Subject to Duty

The Board of United States General Appraisers, New York, has overruled a protest of the Norton Co., Worcester, Mass., relative to the assessment of duty on waste alundum. The alundum, consisting of grains or shavings produced in the process of truing grinding wheels made of the same material (crude artificial abrasive) was classified as waste at 10 per cent ad valorem, under paragraph 384 of the tariff act of 1913. The Norton Co. claimed that the material was entitled to free entry as a crude artificial abrasive under paragraph 479. The evidence submitted in the judgment of the board, failed to sustain the protest.

German Plants Close Down

During the past week the dye works at Höchst-am-Main and the Chemischefabrik at Griesheim have been closed down owing to labor disputes, the owners refusing to grant increases in wages demanded by the workers, according to a Reuter cable from Berlin.

Holyoke Paper Mills Show Increased Business

The general business situation in the Holyoke section is showing a marked improvement at the present time. The textile mills are all working on a schedule at least approximating full time, while one or two concerns are running two shifts.

The improvement in paper manufacturing, while not so marked, has been notable since Sept. 1. Part of this may be only temporary because of large orders for papeteries for the holiday trade, but there is reason to believe that a slow but steady increase of business in all lines is under way.

The paper business is in good shape for a resumption of activities all along the line, for paper stocks in the hands of merchants are low and consequently the new prices made by the manufacturer are quickly passed on to the consumer, while a stiffening in the price of certain grades of rags caused by the rise of cotton prices leads to the belief that this important raw material has reached its lowest level. The pulp manufacturers have to a large extent worked off their inventories. As this pulp was made from wood cut at the highest level of war prices and worked up into pulp at higher prices than have been reached before or since, they had to take losses during readjustment.

Considering freight rates, it is safe to say that pulp is nearly as low as it has ever been and any further reductions can be brought about only by forced liquidation of remaining stocks or by lowering of freight charges. Some foreign pulp is being offered for sale, but a large part of this is of inferior quality.

As in other sections, nearly all manufacturers curtailed or eliminated their research work—not because they regarded it as a luxury but because every avenue of expense must be cut off until some signs of light appeared. Research work will be continued when finances permit.

Freight Movement Increases

During the week which ended Sept. 17, 853,762 cars were loaded with revenue freight on the railroads of the United States, according to reports just received from the carriers by the Car Service Division of the American Railway Association. This is the largest number loaded during any one week, records show, since the week of Dec. 4, 1920.

The total for the week was 105,644 cars greater than that for the previous week, when, however, the observance of Labor Day resulted in a falling off in traffic. It was, however, 137,404 cars less than were loaded during the corresponding period last year and 141,229 less than during the corresponding period in 1919.

Increases in the loading of all commodities over the week before were reported but in making comparisons, consideration must be given to the fact that the week of Sept. 17 contained six full working days, while there was a holiday during the preceding week. Grain and grain products was the only commodity which showed an increase over the corresponding week last year.

Agricultural Chemists to Meet

No less than 250 agricultural chemists are expected to be in attendance at the thirty-eighth annual convention of the Association of Official Agricultural Chemists which will be held in Washington Oct. 24 to Oct. 26. The drug section of the association is to have the center of the stage at this meeting. At the last annual meeting principal attention was concentrated on fertilizers. Those in charge of arrangements make it clear, however, that fertilizers and other sections are in no way to be neglected.

The principal addresses are to be those of Secretary of Agriculture Wallace, Harvey W. Wiley and Senator E. F. Ladd. Both Dr. Wiley and Senator Ladd are past presidents of the association. Dr. Wiley had not expected to be present at this convention, due to the fact that he expected to submit to an operation for cataract of the eye prior to the date of the meeting. The time for the operation has been postponed, however, until November, which will permit of Dr. Wiley's personal attendance at the convention. Neither Secretary Wallace nor Dr. Wiley has announced his subject as yet, but Senator Ladd will speak on "The Agricultural Chemist and His Influence on Agriculture."

Forecast of Beet Sugar Crop

From late reports, covering practically all factories, the United States Sugar Manufacturers' Association has compiled the following detailed forecast of the forthcoming beet sugar crop:

State	Area Planted, Acres	Area Estimated to Be Harvested, Acres	Estimated Tonnage of Beets, Short Tons	Estimated Production of Sugar, Short Tons
California.....	132,232	119,962	1,092,478	173,361
Colorado.....	214,040	201,307	2,280,763	290,400
Utah.....	112,371	99,965	1,434,195	174,535
Idaho.....	49,096	47,174	475,670	61,825
Michigan.....	158,569	143,563	1,118,360	141,241
Ohio.....	40,213	3,848	322,930	45,747
Wisconsin.....	19,900	18,000	177,000	19,250
Wyoming and Montana.....	29,400	28,000	264,000	35,100
Other States*.....	124,905	119,820	1,077,000	135,900
Total U. S.				
1921-22.....	880,326	812,612	8,242,396	1,077,359
1920-21.....	978,500	872,376	8,546,193	1,090,021

* Includes Nebraska, Kansas, Iowa, Indiana, Illinois, Minnesota and Nevada.

The following factories will not operate during the forthcoming campaign: Hamilton City, New Delhi, Chino and Tracy, Cal.; Las Animas, Lamar and Delta, Col.; Filer, Utah; Waverly and Belmond, Iowa.

The factory located at Fallon, Nev., which has been idle for several years, has been purchased by the Lahonton Valley Sugar Co., of Bay City, Mich., and will be operated during the campaign.

On account of litigation the Hooper, Utah, and Preston, Idaho, factories may not operate, although these factories have considerable acreage planted.

In California the campaign is in full swing, the Spreckels factory being the last to start slicing, on the 17th of September. The crop is reported to be from fair to good.

In the Utah-Idaho district the campaign will not be well under way until the first week in October. The condition of the crop in this section is reported to be exceptionally good, with prospects for a large tonnage.

The crop condition in Michigan is reported as fair to good, while in Ohio it is only fair. With the exception of the Toledo factory slicing will not begin until after the first week of October. Several of the plants do not expect to start until after Oct. 15.

Reports from Colorado indicate an exceptionally good yield this year, both as to tonnage and sugar content. It is expected that by the end of this week most of the factories will be in operation.

To Investigate White Clays and Bauxites of Central Georgia

The Ceramic Experiment Station of the U. S. Bureau of Mines located at Columbus, Ohio, has entered into a co-operative agreement with the Central of Georgia R.R. through its industrial agent, J. M. Mallory, and its president, William A. Winburn, whereby the Ceramic Station is to investigate the white clays and bauxites along the right of way of the railroad, the lines of which pass through about 80 per cent of the white clay and bauxite belt of Georgia. The white clay deposits of Georgia are so numerous and extensive that it can be said that this material is practically inexhaustible. A number of deposits are from 20 to 40 ft. in thickness and cover in many instances as much as 200 acres in extent.

Bauxite beds occur especially in the Cuthbert, Republic and Andersonville districts from 4 to 8 ft. in thickness, and deposits are found which vary in composition all the way from kaolin on the one hand to bauxite on the other. According to the geology of these deposits, which occur on the coastal plain, the bauxites are derived from the alteration of kaolin, which was derived from the decomposition of pragmatite and granitic rocks of the Piedmont plateau to the north of the coastal plain. The kaolin was transported by water from the site of its formation and deposited at the lower level, where it was built up in many instances as much as 25 to 30 and even 40 ft. in thickness. The close association between the kaolins and bauxites indicate that the latter was derived from the former by the action of sulphuric acid produced by the dissociation of large beds of pyrites.

The white clays are being mined at a few points, more especially at Gordon, McIntyre, Claymont and Butler, and sold principally to the fillers trade. Bauxites have been mined in the Cuthbert, Toombsboro and Andersonville districts and find uses principally for the manufacture of alum, aluminum and abrasives. For strictly ceramic purposes very little is known of the physical properties of these materials, known as Georgia kaolin, bauxitic clays and bauxites.

The work, which is to be done under supervision of R. T. Stull, chief ceramist of mines, consists in devising better refining methods and the testing of the physical properties of the materials so prepared. For this purpose twenty-four representative samples of two tons each have been gathered by the Central of Georgia R.R.'s representative, Dr. T. Poole Maynard, and delivered to the Ceramic Station. A small-size washing plant is being constructed at the Ceramic Station capable of handling about 1,000 lb. to a charge. The working properties, drying and burning behaviors, burning color and refractoriness of the different separations in the washing process are to be determined. Chemical analyses of these samples are also to be made, since the analyses are important more especially with respect to the highly aluminous clays and bauxites.

New Directory of Canadian Chemical Industries

The Directory of Chemical Industries in Canada, published by the Dominion Bureau of Statistics, has been revised as of Jan. 1, 1921.

In the present edition there are shown the names of more than 800 firms operating over 1,000 plants in Canada. Geographically, plants operated by these firms fall into the following divisions:

Nova Scotia.....	61	Manitoba.....	51
Prince Edward Island..	8	Saskatchewan.....	7
New Brunswick.....	35	Alberta.....	39
Quebec.....	279	British Columbia.....	91
Ontario.....	431	Total.....	1,002

For convenience of reference, as in the first edition, all the products listed under the different firms have been cross-indexed, so that all the concerns known to be making any one article are found under that heading.

The introductory material includes an article on "Canadian Chemical Industries in the Reconstruction Period—Opportunities for Chemical Progress," by S. J. Cook, chief of the mining, metallurgical and chemical branch, and tables of Canadian imports and exports of chemical and allied products during the fiscal years ended March 31, 1914, 1918 to 1921.

Cause of Disaster at Oppau

It has been ascertained definitely, says a Reuter cable from Berlin, that the disaster at the Badische plant in Oppau, Germany, was caused by the explosion of 4,500 tons of a compound of ammonium sulphate and ammonium nitrate, known as ammoniumsulphatsalt peter, which has hitherto been considered as being absolutely free from danger of explosion.

Wholesale Prices Go Lower

Wholesale prices of chemicals and drugs were a trifle lower in August than they were in July, according to statistics gathered by the Department of Labor. The department's index number for August is 161, as compared with 163 in July and 216 in August, 1920. The average price in 1913 equals 100.

Carbon Black Ruling

Carbon black, when produced directly from coal-tar derivatives, such as naphthalene or creosote, comes under the provisions of the dye and chemical control act, according to a Treasury Department ruling.

To Do Research Work on Glass

The Glass Containers' Association has agreed to station a research man at the Bureau of Standards to do work on the fundamental physical chemistry of glasses.

Personal

Dr. J. T. BARKER has returned to his headquarters at Widness, Lancashire, England, after two months' special work at the North American Chemical Co., Bay City, Mich.

C. W. BOTKIN, who has been doing research on the refining of shale oils at the Colorado School of Mines for the past fifteen months, has accepted a position as head of the chemistry department in the New Mexico College of Agriculture and Mechanic Arts, State College, New Mexico.

M. J. CAVALIER, professor of metallurgy in the University of Toulouse, arrived Oct. 1 at Columbia University, where he will take up his work as French exchange professor. Prof. Cavalier will stay until Oct. 30.

JOHN JOSEPH GORRELL, who was formerly connected with the technical direction bureau of the Aluminum Co. of America, at New Kensington, Pa., is now chemist with the Cambria Steel Co. in its laboratory.

THOMAS J. KEENAN has announced his resignation as secretary-treasurer of the Technical Association of the Pulp and Paper Industry to accept the position of editor of *Paper*, in the organization of which he becomes an officer and stockholder.

Dr. J. W. KIMBALL, formerly research chemist with E. I. du Pont de Nemours & Co., has become associated with the National Aniline & Chemical Co. in a similar capacity.

J. GEORGE LEHMAN, Bethlehem Foundry & Machine Co., Bethlehem, Pa., has been appointed chairman of the organization committee of the Association of Chemical Plant Equipment Manufacturers, recently formed.

JOHN C. LEONARD, for a number of years secretary and treasurer of the Johnston Window Glass Co., Hartford City, Ind., has resigned.

Dr. W. LEE LEWIS, professor of chemistry, Northwestern University, Chicago, is lecturing through the Middle Western States in a campaign of public education on the American dye industry and what the proposed tariff means.

ROBERT S. LUNT has been appointed manager of the Boston, Mass., office of E. I. du Pont de Nemours & Co.

Dr. JAMES W. MCBAIN, one of the group of noted English chemists attending the recent annual meeting of the American Chemical Society, gave an interesting address before the members of the Delaware Chapter of the American Chemical Society, at Wilmington, Del., Sept. 20. He spoke upon the subject of the characteristics of sols, gels and curds.

W. H. RANSOM, for the past two years an executive officer at the Old Hickory powder works of the Government, has become connected with the Celluloid Co., Newark, N. J.

JOHN I. TIERNEY, Washington representative of the Manufacturing Chemists' Association, attended the conference of the state manufacturing associations in Chicago, Sept. 29 and 30, at which the plan for American valuation of imports was discussed.

Obituary

SAMUEL STOCKTON VOORHEES, an engineer chemist who had been a member of the U. S. Bureau of Standards staff for the past eleven years, died at Portland, Me., Sept. 23. Mr. Voorhees had gone to Maine in an effort to better his health, which had been bad for several years. He was fifty-four years of age. Mr. Voorhees received his technical education at Lehigh University and at George Washington University. Prior to joining the Bureau of Standards in 1901, Mr. Voorhees served as a chemist in the research departments of the Pennsylvania, the Southern and the New York Central railroads. Funeral services were held in Cincinnati, Sept. 27.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Oct. 3, 1921.

Business in the heavy chemical market continued to improve during the week and buyers are showing more interest, although they are not inclined to buy much more than their needs. Prices showed a decided tendency to firmness and conditions in the trade are much better than at the beginning of last month. Several of those close to the pulse of trading believe that the last quarter will prove to be the brightest of the year and that the improvement in business will be gradual until after New Year's, when it will be brought to its former normal state. Pressure from foreign sources of supply is lighter on account of labor troubles abroad. Germany especially has been handicapped by labor disputes and by the damage suffered by plants in the Oppau district on account of the explosion there. The situation from the American's point of view, therefore, looks much clearer and has every indication of continued improvement.

Soapmakers are leading domestic consumers in the purchase of chemicals. Many of their requirements have been filled with imported chemicals and among these caustic potash has stood foremost. Paper mills have bought quantities of bleach of domestic origin, but have also taken a great deal of domestic material. Textile mills are buying a variety of chemicals, while glass factories are in the market quite frequently for dense soda ash. Conditions among tanneries seem to be greatly improving and it is believed that some good buying will develop in the very near future. Rumors are current that a short interest has accumulated during the past few weeks in soda ash, and these had a tendency to advance prices. Chemical concerns operating in the basic chemical have bought quite freely, believing that the imports from abroad would make it a good gamble. Labor strikes in England and other countries have restricted the importation of ash, while there are great uncertainties of duty and of shipment. There has been very little heard of imported soda ash during the past few weeks. A stiffening market in cyanide of soda, prussiate of soda and soda ash has been the principal factor in the week's activities. There has been a marked shortage of supplies on the two latter items, especially from importers. Caustic potash has held its recent strength and holders are maintaining firm prices. There have been reductions made by manufacturers of sulphuric and nitric acids. These reductions have not had any serious effect on the market, as sales have been made in the past few weeks at these new figures. Bichromate of potash and oxalic acid are somewhat lower. Small-lot sales of the latter have been quite liberal during the past week.

CHEMICALS

Prices on *carbonate of potash* are easier for the various grades, and the market at the close of the week showed declines. Natural offered for shipment was more plentiful, especially for the 80-85 per cent, and the white calcined was offered around 3c. per lb. There has been a reduction on 66 deg. *sulphuric acid* by makers. Quotations now range from \$17 to \$18 per ton on the 66 deg. acid in tank cars, f.o.b. works. The 60 deg. acid is held at recent levels of \$11@12 per ton. There has been a freer movement noted of late for this chemical at the new prices. Solid *caustic soda* is becoming more firmly established at 4c. per lb. There has been some keen competition among holders of standard goods resulting in the sales of carload lots at slightly lower figures. The offerings of standard brands around the trade are not very heavy and the condition of the market may be described as decidedly fair. Spot *nitrite of soda* was held at 7c. per lb. in most quarters, with transactions noted here and there at slightly lower figures. There has not been very much activity in this chemical and trading is confined chiefly to small quantities. Prices of *ammonium sulphate* are very firm at recent levels. Material in bulk

form at the works is quoted around \$2.15 per 100 lb. Supplies for domestic use are exceedingly scarce and consumers find difficulty locating sufficient supplies. Goods in double bags f.a.s. are held at \$2.50 per 100 lb. *White arsenic* is lower at 5½@6c. per lb. Imported material has had a bad effect on the spot market prices and trading has been of a light routine nature. Higher prices are recorded for spot *prussiate of soda* and it is very doubtful if better than 13c. per lb. could be done on round lot quantities, while sellers in other directions are asking up to 13¼ per lb. Some odd-lot sales went through earlier in the week at 12¾c. a lb. The condition of this market continues quite firm, with inquiries and orders greatly increased. Prices on *soda ash* are holding at the recent advance and the market closed in a firm position. It is understood that sales of large quantities of imported material have been made which have not been delivered. Some large dealers have found themselves confronted with the problem of covering their orders on a rising market. Domestic spot goods in single bags are quoted at \$2.19@2.25 per 100 lb., depending on the seller and quantity. Goods in barrels held at \$2.50@\$2.60 per 100 lb. The *cyanide of soda* market is in a very firm condition and second-hand stocks seemed to be well cleared from the market. The 128 per cent was very firm at 24@25c. per lb., while domestic producers are holding their former quotations of 28@30c. per lb. for the 96-98 per cent. *Zinc chloride* producers are still clinging to their old quotations of 9½@12c. per lb. for the fused and granulated varieties, but are practically out of the market in the face of extremely low prices prevailing for imported material. Large importers quote as low as 6c. per lb. for this material.

COAL-TAR PRODUCTS

Some improvement in buying of intermediates is noticeable, but competition for passing orders continues to hamper the advance in prices. Consumers are still operating conservatively and are not very anxious to take on any additional stocks beyond their present requirements. A moderate amount of selling is recorded in *nitraniline* around 79c. per lb. Some sellers ask up to 82c. per lb., but round lot business can probably be placed slightly under the 79c. level. The market on *dimethylaniline* has stiffened during the past few days and the lowest available quotation for second-hand goods is 42c. per lb., with some holders asking up to 45c. per lb. Most of the low-priced material has been well cleaned out of the market and with production greatly curtailed prices will probably remain firm. Quotations on *beta naphthol* are somewhat steadier, with resellers doing 32@33c. per lb. Makers are maintaining a firm attitude and quote 42c. per lb., although there are constant rumors that any actual round lot orders would not be refused down to 35c. per lb. Manufacturers' prices on *diethylaniline* are lower at \$1@\$1.10 per lb., with only a light demand noted. Makers of *aniline oil* are experiencing some difficulty in turning out large quantities on account of the scarcity of benzene. Figures from producers are quoted at 18@20c. per lb., according to quantity and brand. Resellers are offering material at 17½c. per lb. The retail market appears to have sufficient supplies on hand to meet all requirements and there were rumors around the trade of heavy cuts in quotations, even though the condition of the raw material market is quite uncertain. The demand for *benzoic acid* has fallen off and prices have come down accordingly. The technical is quoted at 50@58c. per lb. and the U.S.P. at 60@65c. The benzene market has continued in its recent firmness. Prices are quite varied, according to the seller. There are some holders asking as high as 49c. a gal. for the pure grade and even at this figure there is very little to be found. Refiners are unable to offer any material on the open market and are experiencing added difficulty in meeting old contracts. Supplies of *naphthalene* are being held by weak resellers, with the demand very light. Offers of flakes are heard around 6¼c. per lb. Manufacturers are still maintaining their old figures of 8½@9¼c. per lb. for the flake and 9½@10½ for the balls, with practically no real sales noted. The *phenol* market has taken on the quiet attitude of the rest of the crudes. Here and there an export inquiry is noted, but no

round lot orders have been seen in the market for some time. Resale material is still held at prices ranging from 8¼@9c. per lb. Government surplus material is being maintained at 12@13c. per lb.

The St. Louis Market

ST. LOUIS, Sept. 30, 1921.

While the market on fine chemicals has been subject to slight fluctuations the past two weeks, the general tone has become much firmer. That the general impression that the bottom in price decline has been reached prevails is reflected in the buying of larger quantities of nearly every item. The market on heavy chemicals shows a similar improvement and many buyers have confidence enough to anticipate their requirements again.

ALKALIS

Caustic soda remains in good demand with price of \$4 per 100 lb., basis 73-75 per cent solid, f.o.b. point of production. *Soda ash* demand is still only fair and manufacturers' schedule prevails. *Bicarbonate of soda* and *sal soda* demand is light, with the former enjoying the better demand of the two, and holding at \$2.60 per 100 lb. in less than carlots.

INDUSTRIALS

Carbon bisulphide is in strong demand, with supplies scarce but prices remaining the same. *Aqua ammonia* demand is very good, with price the same. The *sulphur* demand is routine, with price the same, at \$2.10 per 100 lb. for commercial, in bags.

DRUGS AND PHARMACEUTICALS

Bismuth salts continue to enjoy a good demand. *Salicylic acid* declined 2c., *sodium salicylate* has declined 3c. and *acetyl salicylic* has dropped 2c. per lb. respectively in the past two weeks. As the demand is no lighter these declines are due to competition in manufacture. *Iodides* are in good demand, as are *bromides*. There is a general decline of 5c. per lb. on heavy *bromides*. The *sodium benzoate* demand has eased off. *Zinc stearate* is in good demand, with price the same. *Citric acid* is going normal, with price for imported citric the same as the domestic.

ACIDS

The market on 60 per cent *sulphuric acid* is quiet, with price at \$15@\$16 per ton. The market on the 66 per cent is active, with price still at \$20 per ton. *Nitric acid* demand is quiet. *Hydrochloric* is very slow, with no change in price. The *mixed acids* are likewise very quiet. *Salt cake* enjoys the usual good seasonal demand, with the demand exceeding the available supplies and prices high and firm. On *zinc chloride*, the usual contract withdrawals are being made but no new business is being transacted.

VEGETABLE OILS

Castor oil remains in good demand at price of 11½c. per lb. in heavy returnable drums. *Linseed oil* reached a maximum of 83c. per gal., and has slowly declined and today is quoted at 76c. in cooperage, ex-warehouse, with the demand light. *Turpentine* demand remains the same, with price at 72½c. in 5-bbl. lots.

The Iron and Steel Market

PITTSBURGH, Sept. 30, 1921.

While the general condition of the steel market is probably better than a week ago, it is doubtful whether there is any increase in the actual volume of steel mill bookings, on account of two special factors, the large amount of business that was gathered up in wire products in connection with the advance in prices Sept. 12, and the heavy bookings in sheets in anticipation of the price advances that became effective last week. These two important branches of the finished steel market are naturally quiet at present, the production and shipments being of course heavier than formerly.

The formal reductions in pipe mill products a fortnight ago, chiefly by way of recognizing price cutting from the old lists but carrying some prices below any previous cut rates, does not seem to have had much direct effect upon the volume of demand, but there has been some increase, just as demand was increasing during August.

In bars, shapes and plates, the "heavy rolled products," the showing of the market is not quite clear. The reports commonly made are that business is light in all three lines, but there are some indications that a drive is being quietly made by a number of the mills to book customers up for the near future at special prices and in expectation of establishing slightly higher prices as the open market. It is rumored that on all three products some mills will give regular customers contracts to the end of the year, which virtually means price protection, at 1.60c., though what is openly admitted is only that desirable orders, with specifications attached, and for shipment at mill convenience, are acceptable at this figure.

Whatever may be the details in any given case it is now clear that the steel market as a whole has an upward rather than a downward trend. This condition is not based upon the same volume of demand that used to be required before the war to cause steel prices to advance or even become firm. It is based rather upon the fact of prices having gone farther below actual cost of production than producers are willing to countenance as a permanent condition. Before the war it used to be held that steel prices would not trend upward of their own accord unless mills had an actual operation of better than 75 per cent. In no branch of the finished steel trade, except possibly in sheets and wire products, is there an operation approaching that level, while in those two groups orders were placed by buyers under the spur of an expected price advance, and it is not proved that buying will be resumed at the advanced prices now ruling.

STEEL PRODUCTION

There has been little if any increase in steel production this week as compared with last week, and the general rate, in ingots, may be taken at approximately 33 per cent of capacity. The best demand has been in the lighter lines, sheets, wire products, tubular goods and tin plate, and accordingly the tonnage of steel production is not greatly affected. Bars, shapes, plates and rails show very light production. Probably an upward trend in steel production will continue for a few weeks, bringing about an operation of between 40 and 50 per cent, but unless some radical change occurs in fundamental conditions, such as inception of railroad buying on a fair scale or a large increase in construction work involving steel, no better rate is to be expected, and demand may even taper off in December and January, which are normally dull months in the trade.

The steel mills feel that the price liquidation in finished steel products has been carried too far. Taking the recent prices for wire products and sheets, and current prices for other products, a weighted average shows prices at only 31 per cent above the average level in 1913. The Bureau of Labor's index number of commodities at wholesale, with 1913 standing at 100, was 148 for July and 152 for August, showing an advance and also showing a higher level than obtains in steel, since the index number for steel would be 131.

PIG IRON AND COKE

The pig iron markets throughout the country have continued firm, even though rather inactive. In eastern Pennsylvania there has been a slight advance in the week. The chief activity in the local market has been in purchases by the Standard Sanitary Manufacturing Co., which bought 5,000 tons of foundry iron for its Pittsburgh plant and an equal tonnage for its New Brighton plant, fourth quarter delivery, paying for nearly all the iron the regular price of \$21 valley. The company also bought 5,000 tons for its Louisville plant, taking Southern iron at \$19 Birmingham. Basic remains quotable at \$19 to \$20 valley, and bessemer at \$20.

Connellsville coke is not quotably changed, at \$3.25@\$3.50 for furnace and \$4.25@\$4.75 for foundry, these prices being about 25c. above the average in July and August, the increase being supported by the recent wage advance. Demand on the whole is somewhat better, but the Connellsville trade has been disturbed by the selling of byproduct coke by steel works, requiring the capacity normally for their own requirements. Several operators, formerly indifferent, now seem willing to sell at cost in order to get into operation, trusting to future improvement for profits.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.		\$0 40 - \$0 45
Acetone	lb.	\$0 12½ - \$0 12½	13 - 13½

Aluminum sulphate, iron free	lb.	03 - 03½	03½ - 04
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	07½ - 07½	08 - 08½
Ammonia, anhydrous, cyl. (100-150 lb.)	lb.	30 - 32	33 - 35
Ammonium carbonate, powder	lb.	07 - 07½	08 - 09
Ammonium chloride, granular (white)	lb.	06 - 06½	06½ - 07
Ammonium chloride, granular (gray)	lb.	06½ - 07	07½ - 08
Ammonium nitrate	lb.	07½ - 07½	07½ - 08½
Ammonium sulphate	100 lb.	2 20 - 2 25	2 30 - 2 40
Amylacetate	gal.		3 25 - 3 50
Amylacetate tech.	gal.		2 50 - 3 00
Arsenic oxide, (white arsenic) powdered	lb.	05½ - 05½	06 - 06½
Arsenic, sulphide, powdered (red arsenic)	lb.	11 - 11½	12 - 13
Barium chloride	ton	43 00 - 45 00	46 00 - 49 00
Barium dioxide (peroxide)	lb.	20 - 21	22 - 23
Barium nitrate	lb.	07½ - 08	08½ - 09
Barium sulphate (precip.) (blanc fixe)	lb.	04 - 04½	04½ - 05
Bleaching powder (see calc. hypochlorite)			
Blue vitriol (see copper sulphate)			
Borax (see sodium borate)			
Brimstone (see sulphur, roll)			
Bromine	lb.	27 - 28	28½ - 30
Calcium acetate	100 lbs.	2 00 - 2 05	
Calcium carbide	lb.	04½ - 04½	05 - 05½
Calcium chloride, fused, lump	ton	23 50 - 24 00	24 50 - 25 50
Calcium chloride, granulated	lb.	01½ - 02	02½ - 02½
Calcium bychlorite (bleach'g powder)	100 lb.	2 75 - 2 80	2 90 - 3 50
Calcium peroxide	lb.		1 40 - 1 50
Calcium phosphate, tribasic	lb.		15 - 16
Camphor	lb.		70 - 72
Carbon bisulphide	lb.	06 - 06½	06½ - 07½
Carbon tetrachloride, drums	lb.	10½ - 10½	11 - 12
Carbonyl chloride, (phosgene)	lb.		60 - 75
Caustic potash (see potassium hydroxide)			
Caustic soda (see sodium hydroxide)			
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	08 - 09	09½ - 10
Chloroform	lb.		38 - 43
Cobalt oxide	lb.		2 00 - 2 10
Copperas (see iron sulphate)			
Copper carbonate, green precipitate	lb.	19 - 19½	20 - 21
Copper cyanide	lb.		50 - 62
Copper sulphate, crystals	lb.	05 - 05½	05½ - 06
Cream of tartar (see potassium bitartrate)			
Epsom salt (see magnesium sulphate)			
Ethyl Acetate Com. 85%	gal.		1 00 - 1 10
Ethyl Acetate pure (acetic ether, 93%)	gal.		40 - 42
to 100%	lb.		12½ - 13½
Formaldehyde, 40 per cent.	lb.	12 - 12½	12½ - 13½
Fusel oil, ref.	gal.		3 25 - 3 75
Fusel oil, crude	gal.		1 50 - 1 75
Glauber's salt (see sodium sulphate)			
Glycerine, C. P. drums extra	lb.		14½ - 15
Iodine, resublimed	lb.		3 50 - 3 60
Iron oxide, red	lb.		10 - 20
Iron sulphate (copperas)	ton	18 00 - 19 00	20 00 - 23 00
Lead acetate	lb.		10½ - 12½
Lead arsenate, paste	lb.	09 - 09½	10 - 11
Lead nitrate	lb.		15 - 20
Litharge	lb.	07½ - 08	08½ - 09
Lithium carbonate	lb.		1 30 - 1 40
Magnesium carbonate, technical	lb.	08 - 08½	09 - 10
Magnesium sulphate, U. S. P.	100 lb.	2 50 - 2 75	
Magnesium sulphate, technical	100 lb.		1 10 - 1 75
Methanol, 95%	gal.		66 - 68
Methanol, 97%	gal.		70 - 72
Nickel Salt, double	lb.		12 - 12½
Nickel salt, single	lb.		14 - 14½
Phosgene (see carbonyl chloride)			
Phosphorus, red	lb.	40 - 41	42 - 45
Phosphorus, yellow	lb.		30 - 35
Potassium bichromate	lb.	11 - 11½	11½ - 12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$..... - \$.....	\$0.25 $\frac{1}{2}$ - \$0.28
Potassium bromide, granular..... lb.	 -	.15 - .23
Potassium carbonate, U. S. P..... lb.	.20 - .21	.22 - .25
Potassium carbonate, 80-85%..... lb.	.04 - .04 $\frac{1}{2}$	.05 - .06
Potassium chlorate, crystals..... lb.	.07 - .07 $\frac{1}{2}$	.07 $\frac{1}{2}$ - .10
Potassium cyanide..... lb.	 -	.26 - .28
Potassium hydroxide (caustic potash)..... lb.	.05 $\frac{1}{2}$ - .05 $\frac{3}{4}$	.06 - .08
Potassium muriate, 80% K.C.I..... ton	40.00 - 42.50	 -
Potassium iodide..... lb.	 -	2.60 - 2.75
Potassium nitrate..... lb.	.09 $\frac{1}{2}$ - .09 $\frac{3}{4}$	.10 - .12 $\frac{1}{2}$
Potassium permanganate..... lb.	.20 - .21	.22 - .23
Potassium prussiate, red..... lb.	.28 - .29	.29 $\frac{1}{2}$ - .30
Potassium prussiate, yellow..... lb.	.20 - .20 $\frac{1}{2}$	.21 - .22
Potassium sulphate (powdered)..... per unit	 -	1.20 - 1.25
Rochelle salts (see sodium potas. tartrate)	 -	 -
Salammoniac (see ammonium chloride).....	 -	 -
Salt soda (see sodium carbonate)..... ton	 -	20.00 - 25.00
Salt cake (brk)..... oz.	 -	1.35 - 1.38
Silver cyanide..... oz.	 -	.47 - .48
Silver nitrate..... 100 lb.	2.10 - 2.15	2.20 - 2.50
Soda ash, high..... 100 lb.	2.35 - 2.40	2.45 - 2.70
Soda ash, dense..... lb.	.04 - .04 $\frac{1}{2}$	.04 $\frac{1}{2}$ - .05
Sodium acetate..... 100 lb.	2.00 - 2.25	2.50 - 2.75
Sodium bicarbonate..... lb.	.07 $\frac{1}{2}$ - .08	.08 $\frac{1}{2}$ - .08 $\frac{3}{4}$
Sodium bichromate..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphate (nitre cake)..... lb.	.04 $\frac{1}{2}$ - .05	.05 $\frac{1}{2}$ - .06
Sodium bisulphate powdered, U.S.P..... lb.	.05 $\frac{1}{2}$ - .06	.06 $\frac{1}{2}$ - .07
Sodium borate (borax)..... 100 lb.	1.90 - 2.00	2.10 - 2.40
Sodium carbonate (sat. sol.)..... lb.	.07 $\frac{1}{2}$ - .07 $\frac{3}{4}$	.08 - .08 $\frac{1}{2}$
Sodium chloride..... lb.	.24 - .25	.26 - .30
Sodium cyanide..... lb.	.10 $\frac{1}{2}$ - .11	.11 $\frac{1}{2}$ - .12
Sodium hydroxide (caustic soda)..... 100 lb.	4.00 - 4.10	4.15 - 4.75
Sodium hyposulphite..... 100 lb.	2.20 -	2.35 -
Sodium nitrate..... lb.	.06 $\frac{1}{2}$ - .07	.07 $\frac{1}{2}$ - .07 $\frac{3}{4}$
Sodium nitrite..... lb.	.25 - .26	.27 - .30
Sodium peroxide, powdered..... lb.	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$	.04 $\frac{3}{4}$ - .05 $\frac{1}{2}$
Sodium phosphate, dibasic..... lb.	 -	.21 - .24
Sodium potassium tartrate (Rochelle salts) lb.	.13 - .13 $\frac{1}{2}$	.13 $\frac{1}{2}$ - .13 $\frac{3}{4}$
Sodium prussiate, yellow..... lb.	1.00 - 1.15	1.25 - 1.40
Sodium silicate, solution (40 deg.)..... 100 lb.	.02 $\frac{1}{2}$ - .03	.03 $\frac{1}{2}$ - .03 $\frac{3}{4}$
Sodium silicate, solution (60 deg.)..... 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$	.05 - .06
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.03 $\frac{1}{2}$ - .04	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$
Sodium sulphite, crystals..... lb.	.12 - .13	.13 $\frac{1}{2}$ - .20
Strontium nitrate, powdered..... lb.	.05 - .05 $\frac{1}{2}$	.05 $\frac{1}{2}$ - .06 $\frac{1}{2}$
Sulphur chloride, red..... ton	18.00 - 20.00	 -
Sulphur, crude..... lb.	.08 - .08 $\frac{1}{2}$	.09 - .10
Sulphur dioxide, liquid, cylinders ex. a..... 100 lb.	 -	2.25 - 3.10
Sulphur (sublimed), flour..... 100 lb.	 -	2.00 - 2.75
Sulphur, roll (brimstone)..... lb.	.18 - .19	 -
Tin bichloride, 50 per cent..... lb.	 -	.38 - .40
Tin oxide..... lb.	.16 - .16 $\frac{1}{2}$	.17 - .17 $\frac{1}{2}$
Zinc carbonate, precipitate..... lb.	.09 $\frac{1}{2}$ - .09 $\frac{3}{4}$	.10 - .11
Zinc chloride, gran..... lb.	.42 - .44	.45 - .47
Zinc cyanide..... lb.	.11 $\frac{1}{2}$ - .11 $\frac{3}{4}$	.11 $\frac{3}{4}$ - .12 $\frac{1}{2}$
Zinc dust..... lb.	.07 $\frac{1}{2}$ - .07 $\frac{3}{4}$	.08 - .09
Zinc oxide, XX..... 100 lb.	3.00 - 3.25	3.30 - 3.50
Zinc sulphate.....	 -	 -

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.15 - \$1.20
Alpha-naphthol, refined..... lb.	1.30 - 1.35
Alpha-naphthylamine..... lb.	.30 - .35
Aniline oil, drums extra..... lb.	.17 $\frac{1}{2}$ - .20
Aniline salts..... lb.	.24 - .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.00 - 1.25
Benzidine, base..... lb.	1.00 - 1.10
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.52 - .55
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.50 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.32 - .35
Beta-naphthylamine, sublimed..... lb.	1.90 - 2.00
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .17
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .75
Cresylic acid, 75-97%, dark, in drums..... gal.	.60 - .65
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.00 - 1.15
Dimethylaniline..... lb.	.42 - .50
Dinitrobenzene..... lb.	.25 - .28
Dinitrochlorobenzene..... lb.	.25 - .30
Dinitronaphthalene..... lb.	.32 - .40
Dinitrophenol..... lb.	.37 - .40
Dinitrotoluene..... lb.	.25 - .30
Dip oil, 25%, ear lots, in drums..... gal.	.30 - .35
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.10 - 1.20
Meta-phenylenediamine..... lb.	1.15 - 1.20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.50 - 1.60
Naphthalene, crude, in bbls..... lb.	.06 $\frac{1}{2}$ - .07 $\frac{1}{2}$
Naphthalene, flake..... lb.	.06 $\frac{1}{2}$ - .08
Naphthalene, balls..... lb.	.08 - .09 $\frac{1}{2}$
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.15 - .17
Ortho-amidophenol..... lb.	3.00 - 3.10
Ortho-dichlorobenzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.21 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-nitrophenol, HCl..... lb.	1.70 - 1.80

Para-dichlorobenzene..... lb.	.15 - .20
Paranitroaniline..... lb.	.79 - .82
Para-nitrotoluene..... lb.	.80 - .85
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.40 - .50
Phenol, U. S. P., drums..... lb.	.08 $\frac{1}{2}$ - .10
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.50 - 1.60
Resorcinol, pure..... lb.	2.25 - 2.30
Salicylic acid, tech., in bbls..... lb.	.18 - .20
Salicylic acid, U. S. P..... lb.	.19 - .22
Salol..... lb.	.60 - .70
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.30 - 1.35
Toluidine, mixed..... lb.	.43 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .48
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 -

Waxes

Prices based on original packages in large quantities.

Payberry Wax..... lb.	\$0.19 - \$0.20
Beeswax, refined, dark..... lb.	.24 - .25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.36 - .42
Candelilla wax..... lb.	.24 - .25
Carnauba, Florida..... lb.	.48 - .50
Carnauba, No. 2, North Country..... lb.	.24 - .25
Carnauba, No. 3, North Country..... lb.	.14 $\frac{1}{2}$ - .15
Japan..... lb.	.24 - .26
Montan, crude..... lb.	.05 - .05 $\frac{1}{2}$
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03 $\frac{1}{2}$ - .03 $\frac{3}{4}$
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 -
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .03 $\frac{1}{2}$
Paraffine waxes, refined, 125 m.p..... lb.	.03 $\frac{1}{2}$ - .03 $\frac{3}{4}$
Paraffine waxes, refined, 128-130 m.p..... lb.	.03 - .04 $\frac{1}{2}$
Paraffine waxes, refined, 133-135 m.p..... lb.	.04 $\frac{1}{2}$ - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 $\frac{1}{2}$ - .06
Stearic acid, single pressed..... lb.	.09 -
Stearic acid, double pressed..... lb.	.10 $\frac{1}{2}$ -
Stearic acid, triple pressed..... lb.	.11 - .11 $\frac{1}{2}$

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.55 - 5.65
Rosin E-I..... 280 lb.	5.75 - 6.25
Rosin K-N..... 280 lb.	6.35 - 6.75
Rosin W. G.-W. W..... 280 lb.	6.90 - 7.40
Wood rosin, bbl..... 280 lb.	6.25 -
Spirits of turpentine..... gal.	.75 -
Wood turpentine, steam dist..... gal.	.73 -
Wood turpentine, dest. dist..... gal.	.72 -
Pine tar pitch, bbl..... 200 lb.	 - 6.50
Tar, kiln burned, bbl. (500 lb.)..... bbl.	 - 11.00
Retort tar, bbl..... 500 lb.	 - 11.00
Rosin oil, first run..... gal.	.35 -
Rosin oil, second run..... gal.	.37 -
Rosin oil, third run..... gal.	.44 -
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	1.90 -
Pine oil, pure, dest. dist..... gal.	1.50 -
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 -
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 -
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 -
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35 -
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.25 -
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990..... gal.	.35 -
Pinewood creosote, ref..... gal.	.52 -

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 -
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 -
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 -
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 -

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 - .21 $\frac{1}{2}$
Upriver coarse..... lb.	.11 $\frac{1}{2}$ - .12
Upriver caucho ball..... lb.	.11 $\frac{1}{2}$ - .12
Plantation—First latex crepe..... lb.	.15 $\frac{1}{2}$ - .15 $\frac{3}{4}$
Ribbed smoked sheets..... lb.	.15 $\frac{1}{2}$ - .15 $\frac{3}{4}$
Brown crepe, thin, clean..... lb.	.15 -
Amber crepe No. 1..... lb.	.17 -

Oils

VEGETABLE

The following prices are f.o.b. New York for earload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.09 $\frac{1}{2}$ - \$0.09 $\frac{3}{4}$
Castor oil, AA, in bbls..... lb.	.11 - .11 $\frac{1}{2}$
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.14 $\frac{1}{2}$ - .15
Cocoonut oil, Ceylon grade, in bbls..... lb.	.10 - .10 $\frac{1}{2}$
Cocoonut oil, Ceylon grade, in bbls..... lb.	.10 $\frac{1}{2}$ - .11
Corn oil, crude, in bbls..... lb.	.09 - .09 $\frac{1}{2}$
Cottonseed oil, crude (f. o. b. mill)..... lb.	.08 - .08 $\frac{1}{2}$
Cottonseed oil, summer yellow..... lb.	.10 - .10 $\frac{1}{2}$
Cottonseed oil, winter yellow..... lb.	.10 $\frac{1}{2}$ - .11
Linseed oil, raw, ear lots (domestic)..... gal.	.73 - .74
Linseed oil, raw, tank cars (domestic)..... gal.	.67 - .68
Linseed oil, in 5-bbl. lots (domestic)..... gal.	.76 - .77

Olive oil, Denatured.....	gal.	\$1.10	—	\$1.20
Palm, Lagos.....	lb.	.08	—	.08½
Palm, Niger.....	lb.	.06½	—	.06½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08½	—	.09
Peanut oil, refined, in bbls.....	lb.	.11	—	.11½
Rapeseed oil, refined in bbls.....	gal.	.87	—	.89
Rapeseed oil, blown, in bbls.....	gal.	.91	—	.92
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.09	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.07½	—	

FISH

Light pressed menhaden.....	gal.	\$0.40	—	
Yellow bleached menhaden.....	gal.	.42	—	
White bleached menhaden.....	gal.	.44	—	
Blown menhaden.....	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04	—	.04½
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.07	—	.10
Chalk, Precipitated, domestic, extra light.....	lb.	.04½	—	.05
Chalk, Precipitated, domestic, light.....	lb.	.04	—	.04½
Chalk, Precipitated, domestic, heavy.....	lb.	.03½	—	.04
Chalk, Precipitated, English, extra light.....	lb.	.04½	—	.05
Chalk, Precipitated, English, light.....	lb.	.04½	—	.05
Chalk, Precipitated, English, dense.....	lb.	.04	—	.04½
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	13.30	—	20.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

CAMDEN—H. M. Jones, El Dorado, Ark., and associates, are planning for the erection of a new oil refinery at Camden, to consist of 2 units, with initial daily output of about 500 bbl.

California

RICHMOND—The Pacific Sanitary Mfg. Co., Fifth and Hensley Sts., manufacturer of sanitary ware, will commence the immediate construction of a 1-story addition to its plant, 100 x 300 ft. The erection contract has been let to Carl Overa, 2105 Roosevelt St.

LOS ANGELES—The Los Angeles Fabricating Co. has filed plans for the erection of a new 1-story steel fabricating plant, 95 x 160 ft., estimated to cost about \$80,000. The Austin Co., Los Angeles, has the construction contract.

VISTA—The Sierra Clay Products Co., Sparks, Nev., H. O. Hague, president, is planning for the construction of a new brick-manufacturing plant at its clay properties in the Truckee River canyon, near Vista. The initial plant will be supplemented at an early date by a works for the manufacture of pottery and other burned clay products.

Florida

LEESBURG—The Grass Fibre Pulp & Paper Corp., recently organized with a capital of \$1,000,000, has construction under way on its new local plant to be equipped for the manufacture of paper pulp from sawgrass. The works will have an initial capacity of about 40 tons. It is planned to have the factory ready for operation at an early date. W. F. Stovall is president; and E. R. Lacey, vice-president and general manager.

Indiana

INDIANAPOLIS—The Parker Tire & Rubber Co., 264 Allen Ave., will hold in abeyance the completion of unit No. 2, at its tire-manufacturing plant. The foundation work for the structure has been completed; it will be 2-story, 100 x 600 ft., and is estimated to cost about \$300,000, with machinery. Paul P. Parker is president. George L. Whitsit, company address, is engineer.

MARION—The Upland Flint Bottle Co. has resumed production at its plant, after a shutdown of several weeks, giving employment to about 250 men.

Kentucky

SMITHFIELD—The Ohio-Kentucky Fluorspar & Lead Co., recently organized, is planning for the installation of equipment on properties acquired, previously operated by the North American Co. The present plant has a capacity of about 150 tons per day, and this output will be doubled. The company is capitalized at \$1,000,000. F. B. Moody is general manager.

Massachusetts

PEABODY—The Morse Blacking Co. has commenced the construction of an addition to its plant, 1-story, 22 x 125 ft. A portion of the structure will be equipped as a laboratory and the remainder for the manufacture of color-finishes for leather tanning work.

BOSTON—The Massachusetts Oil Co. is perfecting plans for the construction of a new branch works on Pequot Ave., New London, Conn.; it will consist of a number of buildings.

CHARLESTON—Fire, Sept. 16, destroyed a portion of the 3-story works of the Eastern Metal & Refining Co., 60 Roland St., with loss estimated at about \$18,000.

Mississippi

JACKSON—The Central Cotton Oil Co. is reported to be planning for the immediate rebuilding of the portion of its plant, destroyed by fire Sept. 14, with loss estimated at about \$75,000.

New Jersey

NEWARK—The Krepecraft Co., recently organized with a capital of \$20,000, has leased a portion of the plant of the Universal Caster & Foundry Works, Jackson Ave., for the establishment of a new plant for the manufacture of crepe-paper products. The structure consists of a total of about 8,000 sq. ft. of floor space, and will be remodeled and equipped immediately for the new line of manufacture. The office of the company will be located at 129 Jackson Ave. Fred E. Rothermel and Fred Schuler head the company.

BELLEVILLE—The Bob White Chemical Co., 39 Broadway, New York, N. Y., is planning for the construction of a new plant in the vicinity of Belleville. Application for permission to erect the structure has been made to the local town officials. The company is perfecting plans for the erection of a new laboratory and works structure at Ogdensburg, N. Y. It was formerly known as the Morgan Chemical Co.

TRENTON—The Star Porcelain Co., Muirhead Ave., manufacturer of electrical porcelain products, is taking bids for the erection of a 1-story addition to its plant, 50 x 82 ft.

NEWARK—The Art Metal Works, 7 Mulberry St., is arranging for the immediate installation of a new gas-recovery system at its branch works at 45 Manufacturers Pl.

New York

ALBANY—The Pittsburgh Plate Glass Co., Pittsburgh, Pa., and 103 Hunters Point Ave., Long Island City, N. Y., has awarded a contract to Bame & Cardell, Central Ave., Albany, for the erection of a new local plant on Tivoli St., to be 2-story, 103 x 180 ft., and consisting of a factory, power house and warehouse.

MECHANICVILLE—Fire, Sept. 16, destroyed a portion of the plant of the Duffney Brick Co., including drying department, boiler and engine rooms, and other works departments, with loss estimated at close to \$200,000, including equipment. The plant will be rebuilt.

SYRACUSE—The Onondaga Pottery Co., 1858 West Fayette St., has commenced excavations for its new pottery on Court St. for the manufacture of general ware, estimated to cost in excess of \$300,000 with machinery. The building contract has been awarded to Dawson Bros., Union Bldg. B. E. Salisbury is president.

Ohio

CLEVELAND—The Rail Welding & Bonding Co., 2400 Woodland Ave., has awarded a contract to the Austin Co., 16122 Euclid Ave., for the erection of a 1-story and basement plant addition, 90 x 180 ft.

CUYAHOGA FALLS—The Duro Brick Mfg. Co. is perfecting plans for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about \$75,000.

AKRON—The Mason Tire & Rubber Co. is arranging for enlargements in its plant to double, approximately, the present capacity. A portion of the present works will be remodeled to accommodate the installation of considerable new machinery. It is proposed to have the entire plant ready for service early in the coming year, with output of about 4,000 tires and 4,000 tubes per day.

CANTON—Fire, Sept. 14, destroyed a portion of the plant of the Republic Rubber Co., with loss estimated at about \$20,000.

TOLEDO—The Spltzer Paper Box Co., 3501 Monroe St., has awarded a contract to the Henry J. Spieker Co., Elm and Utica Sts., for the erection of its proposed 3-story

plant addition, 30 x 80 ft., estimated to cost about \$50,000. George R. Rheinfrank, Gardner Bldg., is architect.

Oklahoma

MUSKOGEE—The Oklahoma Producing & Refining Co. is planning for extensions and improvements in its local oil refinery. It is proposed to increase the production by about 20,000 bbl. a month; a number of new stills will be installed, and the storage capacity increased to about 350,000 bbl. of crude oil and 110,000 bbl. of refined products. The work, including equipment, is estimated to cost about \$150,000. Meadquarters of the company are at Tulsa, Okla.

Pennsylvania

READING—The Electric Manganese Steel Co. is completing plans for the erection of a new 1-story foundry in the Brush Valley section, to be 1-story, 40 x 140 ft., and estimated to cost about \$50,000. It will be equipped for the manufacture of steel castings. William H. Dechant & Son, Baer Building, are engineers.

EASTON—The Forbes Aluminum Products Co., recently organized under Delaware laws with capital of \$500,000, has plans in preparation for the erection of a new local plant, estimated to cost in excess of \$100,000. The company is represented by the Corporation Trust Co. of America, du Pont Bldg.

NEW CASTLE—Frank A. Seiberling, president of the Lehigh Tire & Rubber Co., formerly the New Castle Tire & Rubber Co., is said to be negotiating for the purchase of the plant and property of the Portage Tire & Rubber Co., Portage, Ohio, now operating under a receivership, with an offer of \$750,000 for the assets. Upon acquisition, the plant will be operated in conjunction with the local works. Mr. Seiberling was previously head of the Good-year Tire & Rubber Co.

Tennessee

JELLICO—The Jellico Firebrick Co. is arranging for the immediate installation of new equipment at its plant for the manufacture of firebrick, facebrick and other burned clay products. The company recently filed articles of incorporation with a capital of \$100,000. Frank L. Smith is secretary and treasurer.

Texas

MEXIA—The Mexia Refining Co., Telephone Exchange Bldg., has awarded a contract to Charles V. Miller, Fort Worth, Tex., for the erection of its proposed new local oil refinery. The plant will be equipped to develop an output of about 3,000 bbl. a day, and is estimated to cost about \$250,000. The machinery installation is expected to aggregate \$150,000 in cost. Construction will be inaugurated at once.

ROTAN—The Patton Cement Plaster Co., recently organized with a capital of \$350,000, is arranging for the erection of a local plant for the production of plaster. It is proposed to develop a capacity of about 400 tons of material a day. An elevator, 75x300 ft., will be constructed. J. W. Patton is president, and E. W. Maben, secretary and treasurer.

MARSHALL—The Darco Corp., du Pont Bldg., Wilmington, Del., a subsidiary of the du Pont Powder Co., of the same address, has acquired a tract of property at Marshall, totaling 160 acres, to be used as a site for its proposed new plant for the manufacture of Darco, a product produced from lignite and to be used in connection with the manufacture of glucose and kindred specialties. The new plant is estimated to cost about \$1,500,000, and will be equipped to give employment to about 500 men.

AUSTWELL—The Austwell Oil Mill Co. is reported to be planning for the immediate rebuilding of the portion of its plant, recently destroyed by fire.

GORMAN—The Shell Torpedo Co., recently organized, has commenced the erection of a new plant on local site for the manufacture of nitroglycerine and other explosive products. The initial works will have a capacity of 1,200 qt. of material per day. Frank Kirk is president, and A. W. Samberson, vice-president and general manager.

Utah

SALT LAKE CITY—The Utah Iron & Steel Co. has preliminary plans under way for the erection of a number of additions to its works at Midvale, Utah, to include a new blast furnace, sheet mill, general rolling mill and other subsidiary buildings, estimated to cost about \$3,000,000, complete.

The company has increased its capital from of \$2,500,000 to \$5,000,000, with 50,000 shares of common stock, no par value, to finance the expansion.

Virginia

BARBER—The Ohio C. Barber Lime Co., affiliated with the Ohio C. Barber Fertilizer Co., Akron, O., is now operating at its new local plant, producing lime from a natural deposit without burning. Extensive capacity is planned. The company was organized recently with a capital of \$600,000. Clarence W. Perkins is president.

New Companies

THE BULLET PROOF & NON-SHATTERABLE GLASS CORP., New York, N. Y., has been incorporated with a capital of \$500,000, to manufacture special glass products. The incorporators are B. C. Fox, S. Tekulsky and P. Abrams. The company is represented by Hartman, Sheridan & Tekulsky, 152 West 42d St.

THE ROGERS FOUNDRY Co., Detroit, Mich., has been incorporated with a capital of \$35,000, to manufacture iron, steel and other metal castings. The incorporators are C. O. Rogers, Monroe, Mich.; William Reinhold and Alexander Hungler, 448 Yale St., Detroit.

THE BOLIVAR COTTON OIL Co., Bolivar, Tenn., has been incorporated with a capital of \$75,000, to manufacture cotton oil products, with plant at Shelby, Miss. The incorporators are L. B. Wilkinson and C. T. Jacobs, both of Bolivar.

THE MOLDED PRODUCTS Co., Boston, Mass., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture composition and molded products of various kinds. Henry L. F. Kreger is president; and Bennett Sanderson, Littleton, Mass., treasurer.

WELSEY & Co., INC., Brooklyn, N. Y., has been incorporated with a capital of \$20,000, to manufacture oils, greases, etc. The incorporators are M. V. and R. S. Welsey, and F. M. Hill. The company is represented by E. J. Treacy, 15 Park Row.

THE ESSENTIAL OIL Co., New York Ave. and Mulberry St., Trenton, N. J., has been incorporated with a capital of \$250,000, to manufacture oil products. The incorporators are John F. Wharton, August G. Roesele and Harry J. Engels.

THE OHIO VALLEY FLUORSPAR Co., Cave In Rock, Ill., has been incorporated with a capital of \$60,000, to operate fluorspar and other mineral properties and refineries. The incorporators are C. R. Hamilton, U. G. Gullett and C. E. Seward, Cave In Rock.

THE CHIPLEY LEATHER MFG. Co., Chipley, Fla., has been incorporated with a capital of \$25,000, to manufacture leather products. A local plant is now in course of construction. J. B. Guess, Jr., is president; and W. H. Faust, secretary and treasurer.

THE PATUXENT CLAY PRODUCTS Co., 32 South Calvert St., Baltimore, Md., has been incorporated with a capital of \$1,000,000, to mine and manufacture clay products; operate a refinery for metal ore reduction, and kindred manufacture. The incorporators are Henry N. Hanna, Arthur R. Kasson and Herbert W. Holmes.

THE TRINITY OIL CORP., Wilmington, Del., has been incorporated with a capital of \$3,000,000, to manufacture refined petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE KAISER-RADICK CORP., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are J. D. Kaiser, H. I. Dorn and C. M. Rose. The company is represented by Samuel Sperling, 1540 Broadway.

THE CHEMICAL DEVELOPMENT Co., 73 Eppert St., East Orange, N. J., has filed notice of organization to manufacture chemical products. Paul D. Manning, 133 Washington Ave., represents the company.

THE PETROLEUM PRODUCTS Co., Jacksonville, Fla., has been incorporated with a capital of \$25,000, to manufacture oil products. B. E. Bennett is president; H. R. Simcox, secretary; and J. G. Woods, treasurer.

THE PURE LINE Co., New York, N. Y., has been incorporated with a capital of \$10,000, to manufacture chemicals and affiliated products. The incorporators are I. Cole, J. F. Kunzman and S. F. Mead, 158 West 50th St.

THE VALLEY FOUNDRY Co., Cumberland R. I., has been incorporated with a capital

of \$50,000, to manufacture iron, steel and other metal castings. The incorporators are M. M. McKenna and Walter L. Slims, Cumberland; and Frank Gross, 120 Hutchings St., Roxbury, Mass.

THE NON-ACID FERTILIZER & CHEMICAL Co., Lakeland, Fla., has been incorporated with a capital of \$600,000, to manufacture chemical and fertilizer products. C. W. Dean is president; H. E. Memmlinger, vice-president and treasurer; and T. L. Willson, secretary, all of Lakeland.

THE SCHOENFELD-GUTTER Co., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture magnifying glass and other glass products. The incorporators are M. and P. Schoenfeld, and L. Gutter. The company is represented by D. E. Goldfarb, 35 Nassau St.

THE CHEMICAL SALES Co., 356 East Illinois St., Chicago, Ill., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture and deal in chemical products. The incorporators are Joseph Cohen and Aaron T. Rubin.

THE WATTS-JAY Co., Jacksonville, Fla., has been organized under state laws to manufacture fertilizer products. Lemuel P. Jay is president; and John W. Watts, Jr., secretary and treasurer, both of Jacksonville.

THE MOHAWK TANNING Co., Gloversville, N. Y., has been incorporated with a capital of \$10,000, to manufacture leather products. The incorporators are S. F. Sackheim, M. Barnett and O. Brauns. The company is represented by W. S. Cassidy, Gloversville.

THE BEAR RUBBER MILLS CORP., San Antonio, Tex., has been incorporated under Delaware laws with capital of \$1,000,000, to manufacture rubber products. The incorporators are Donald E. Cameron, Charles Massey and Claude J. Kelly, San Antonio. The company is represented by the United States Corporation Co., 65 Cedar St., New York, N. Y.

THE HAYWARD RUBBER Co., Philadelphia, Pa., has been incorporated under Delaware laws with a capital of \$200,000, to manufacture tires and other rubber products. The incorporators are William C. and L. T. Zimmerman, Philadelphia; and E. C. Boyd, Wilmington, Del. The company is represented by Harry P. Joslyn, Ford Bldg., Wilmington.

THE FARADOX RADIUM LABORATORIES, INC., 1012 North Clark St., Chicago, Ill., has been incorporated with a capital of \$30,000, to manufacture radium and radioactive products. The incorporators are Burrell J. Cramer, Frank D. Levan and Harry Linder.

THE JOHN & PETERSON OIL CORP., Tulsa, Okla., has been incorporated with a capital of \$150,000, to manufacture petroleum products. The incorporators are Willard John, J. P. Peterson and Charles P. Yadon, all of Tulsa.

HERBERT S. MICHAEL, INC., 1701 North Charles St., Baltimore, Md., has been incorporated with a capital of \$100,000, to manufacture chemicals and affiliated specialties. The incorporators are Herbert S. Michael, LeRoy R. Hatter and Clayton C. Dobbs.

THE AMERICAN BRASS & ALUMINUM FOUNDERS Co., 6833 South Irving Ave., Chicago, Ill., has been incorporated with a capital of \$35,000, to manufacture brass, bronze, aluminum and other metal castings. The incorporators are Robert C. Fingol, Harry J. Sanding and Anton A. Sikora.

THE COLUMBIA REFINING Co., Cleveland, O., has been organized under Delaware laws to manufacture refined oil products. The incorporators are Rosecoe M. Ewing, James L. Lind and R. C. Heil, Cleveland. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE THUNDERBOLT POWDER Co., Wilmington, Del., has been incorporated under state laws with capital of \$100,000, to manufacture powder, explosives and kindred products. The company is represented by the Capital Trust Co., Dover, Del.

THE SUPERIOR ALUMINUM CORP., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture aluminum and other metal products. The incorporators are W. Bichwit, S. Brodsky and G. C. Woolf. The company is represented by J. L. Bernstein, 5 Beekman St.

THE OLEAN WASH PAINT & VARNISH REMOVER Co., Syracuse, N. Y., has been incorporated with a capital of \$10,000, to manufacture chemical compounds and affiliated specialties. The incorporators are F. P. Malpass, G. W. Fox and E. L. Day. The company is represented by Higbee & Malpass, University Block, Syracuse.

THE T. C. OIL CORP., Columbia, S. C., has been incorporated under Delaware laws with a capital of \$200,000, to manufacture refined oil products. The incorporators are R. A. Cooper and W. A. McSwain, Columbia; and T. C. Hadley, Montgomery, Ala. The company is represented by the American Guaranty & Trust Co., Wilmington, Del.

THE METALLOY Co. OF BALTIMORE, Baltimore, Md., has been incorporated with a capital of \$10,000, to manufacture metal products. The incorporators are John L. Brown, Louis S. Houghton and William B. Rearick, 1728 Mulliken St.

THE PALO MOTOR OIL Co., 38 North Clark St., Chicago, Ill., has been incorporated with a capital of 50 shares of stock, no par value, to manufacture petroleum products, lubricating oils, etc. The incorporators are Harry J. Myerson, William H. Treder and Harry Berger.

Capital Increases, Etc.

THE WORLD'S FERTILIZER PROCESS Co., Sharpsburg, Pa., manufacturer of fertilizer products, has filed notice of increase in capital from \$200,000 to \$500,000.

THE CORRUGATED PAPER PRODUCTS Co., 221 West 26th St., New York, N. Y., has filed notice of increase in capital from \$25,000 to \$125,000.

THE PORTAGE TIRE & RUBBER Co., Portage, O., has filed a petition in bankruptcy, with estimated liabilities stated at \$1,705,000, and assets about \$400,000.

THE ADVANCE COLOR Co., 833 Magnolia Ave., Elizabeth, N. J., has filed a petition in bankruptcy.

THE ZEGLER TIRE & RUBBER Co., 1346 Rawson St., Chicago, Ill., has filed notice of change of name to the Chicago City Rubber Works, Inc.

THE BISON CHEMICAL Co., Buffalo, N. Y., has filed notice of dissolution under state laws.

THE SUPERIOR CHEMICAL Co., Joliet, Ill., has filed notice of change of name to the Calbakpo Co., at the same time changing its headquarters to 4100 Fillmore St., Chicago, Ill.

THE FEDERAL CHEMICAL Co., Nitro, W. Va., has filed notice of increase in capital from \$250,000 to \$500,000.

DAVID E. ALLEN, INC., Yonkers, N. Y., operating a foundry for the manufacture of metal castings, has filed notice of increase in capital from \$25,000 to \$75,000.

THE MAGNOLIA PETROLEUM Co., Dallas, Tex., has filed notice of increase in capital from \$15,994,941 to \$27,460,134.

THE HAMILTON NOVELTY GLASS Co., 2344 West Harrison St., Chicago, Ill., has filed notice of change in name to the Hamilton Glass Co.

Manufacturers' Catalogs

THE WHEELER CONDENSER & ENGINEERING Co., Carteret, N. J., has just received from the printer its catalog on "Wheeler Condensers," which illustrates and describes a complete line of condensers and accessories for stationary and marine service—including Wheeler condensers, vacuum pumps, centrifugal pumps, cooling towers, condenser tubes, feed-water heaters, etc. Among the recent engineering improvements are: A new design of a 26-in. vacuum surface condensing equipment adapted for engine work and dispensing with combined auxiliary pumps; the steam jet air pump, with combined inter-condenser and heater operating at a maximum efficiency without complicated and expensive accessories; the jet condenser, with expansion joint between condenser body and a turbine, and a centrifugal pump having a special vertically split casing. In a section devoted to Crescent Brand condenser tubes, the precision that enters into each step of the manufacture of the highest quality tubes is explained. A condenser data sheet is included with each copy.

THE AUTOMATIC & ELECTRIC FURNACES, LTD., London, has sent a copy of its new catalog describing Wild Barfield electric furnaces, showing the wide range now manufactured by this company. Attention is called to Bulletin 20, which has been written with the idea of explaining to works employees that the best results in hardened steel are obtained by hardening at the non-magnetic point.

THE BROWN HOISTING MACHINERY Co., Cleveland, O., has produced a new clam-

shell bucket which is a powerful digger and has manganese steel digging edges which can be replaced when worn. Bronze bushings are used and throughout the bucket is designed to reduce wear. This is all described in a leaflet which will be furnished upon request to anyone interested.

THE STEERE ENGINEERING CO., Detroit, Mich., has issued a leaflet on Purifier Trays.

THE GRINNELL CO., INC., Providence, R. I., has issued two catalogs: One describing the complete line of textile driers manufactured by the drier division of this company, and the other giving data on the compartment driers used in the chemical, pharmaceutical, dyestuff and color industries. Illustrations and specifications are given. Copies will be sent to anyone interested.

THE COLORADO IRON WORKS CO., Denver, Col., is distributing two leaflets, on "The Skinner Roaster" and "The Akins Flotation and Aeration Machine."

THE DAYTON-DOWD CO., Quincy, Ill., announces its new catalog, No. 246, on centrifugal fire pumps. Numerous photographs of installations and tests are shown.

THE ASHLAND FIREBRICK CO., Ashland, Ky., calls attention to four bulletins which have just been published, on "Firebrick for Rotary Cement Kilns," "Boiler Settings," "Firebrick for Glass Plants" and "Refractories for Oil-Burning Furnaces."

THE YOUNGSTOWN BOILER & TANK CO., Youngstown, O., has issued Bulletin 400, covering its tanks for the storage of gasoline, alcohol, benzene, asphalt, grease, brine, fuel oil, water, oils, soap, benzene, chemicals, etc. Illustrations are given of the different types, and purposes, together with a table of capacities.

THE EASTON CAR & CONSTRUCTION CO., Easton, Pa., in its bulletin on "Quarry Car Practice" illustrates and describes cars used by cement mills.

THE CARRIER ENGINEERING CORP., Newark, N. J., issues each month an interesting booklet entitled "The Weather Vein." The May issue was called the "Drying Number," the June issue the "New Home Number," the July issue the "Dehumidification Number," the August issue "The Motion Picture Number," the September number the "Ceramic Number." Many interesting articles are included in these booklets on air conditioning to the practical requirements of industry.

THE PALO CO., New York City, has issued a leaflet on the New Spencer Abbe refractometer which is illustrated and described.

THE WESTINGHOUSE ELECTRIC & MFG. CO., East Pittsburgh, Pa., in a leaflet just issued describes in detail the auto-transformer, switching mechanism, the contacts, the overload relays, and many other features of type A auto-starters.

THE MANISTEE IRON WORKS CO., Manistee, Mich., has issued Bulletin 7, on "Manistee Vacuum Evaporators." Single and multiple effect units are described, together with a general synopsis of the salt industry, past and present, and the principle and economy of vacuum evaporation as applied to concentration and crystallization.

THE DORR CO., New York, in Bulletin No. 16 illustrates and describes continuous agitation and continuous counter-current washing in the chemical industries.

THE DOVER BOILER WORKS, New York, has issued specification and notes on steel stacks and tanks for factories, power houses, office, loft and apartment buildings, etc. This booklet contains a practical non-technical form of specification, with supplementary shop notes for the use of architects and engineers.

THE AMERICAN ROLLING MILL CO., Middletown, O., has issued an attractive publication, "Arnico in Picture and Fact." This is a well printed and bound piece of publicity on behalf of a well-known American product. Manufacture of ingot iron sheets is shown by a series of a hundred or more excellent photographs, each operation being described briefly in a caption. Then comes a section showing the various forms of roofing and roofing accessories, culvert pipe, small tanks, etc., which are made at the main plant. Finally about 80 pages are devoted to a comprehensive set of tables of weights of sheets and plates of various gages, lengths and finishes.

THE KEWANEE BOILER CO., Kewanee, Ill., has issued Catalog 76, covering complete data on Kewanee firebox boilers, including drawings and dimensions.

THE M. W. KELLOGG CO., New York, calls attention to a new attractive book on

"Power Plant Piping." This company, which has been called upon to solve many intricate piping problems, has gathered the more important elements of this knowledge and has crystallized them into the story which is contained in this book. It deals with the scope of its service, specifications for piping, the different kinds of pipes and piping, the size and design of the piping system, expansion of pipes, fittings, flanges, flow of water and steam, joints, etc. Another publication just issued by this company is on "Kellogg Hammer Welding" which is a process of making leak-proof vessels for the chemical industries. Both these catalogs are well illustrated.

THE STANDARD CAP & SEAL CORP., Chicago, Ill., has issued a booklet on "Standard Capping Machines," both hand or power operated.

THE LINK-BELT CO., Chicago, Ill., in its new steel chain data book 475 describes the heavier rugged steel chains used for power transmission, and also elevating and conveying chains. In book 215 this company describes the Uniroll and Multiroll idlers, and give also the correct method of figuring belt conveyors, price lists which will enable the user to determine the cost of a complete conveyor or any portion of a conveyor, examples suggesting correct type of belt conveyors and illustrations of typical installations.

THE HARBISON-WALKER REFRACTORIES CO., Pittsburgh, Pa., has issued a leaflet on "Metakase Magnesite Brick" for electric steel furnaces.

F. J. RYAN & CO., Philadelphia, has issued two leaflets: "Mircs Universal Oil Burner" and "Mircs Oil Fired Portable Rivet Heating Furnace." Copies of these bulletins will be sent upon application.

THE DANIEL M. LUEHRS CO., Cleveland, O., has issued two circulars describing its patented electrically heated oil systems. The Oil-Roasting System was designed primarily for the roasting of food products in deep fat or vegetable oils and the Liquid Heat System was designed to maintain temperature in pipe lines, pumps, asphalt and tar roofing machinery, jacketed kettles and evaporators. The heart of these systems consist of the electric oil heater and method of controlling the temperature. The oil-roasting system can be adapted for such work as paraffine impregnation and the heating of paraffines and other solids having a melting point less than 550 deg. F. and which will melt free and not clog up the pump or heater. Inasmuch as the electric heaters operate at a temperature only a few degrees higher than the temperature of the oil leaving the heater, the danger from carbonizing is greatly reduced. This makes it possible to use this system where accurate temperature control is desired and where material is liable to injury due to high temperatures.

THE GEORGE J. HAGAN CO., Pittsburgh, Pa., has issued four new catalogs. Bulletin LF 103 is on liquid fuel burners for the generation of steam; Bulletin LF 104 is on auxiliary apparatus for storing, transporting and conditioning liquid fuels; Bulletin LF 102 is on oil burners for combination oil and gas burners for industrial furnace application, and Bulletin LF 105 is on standardized heat treating furnaces of the combustion type for steel hardening, carbonizing, and annealing—non-ferrous metal annealing and similar metal heating operations. Each booklet is well illustrated.

THE HARDINGE CO., New York, calls attention to Section 1 of its No. 7 catalog, which has been revised and which embraces both wet and dry grinding problems. This section deals with the principle of operation of the conical mill and gives a general description of its uses in the industrial, mining and special fields.

THE YARNALL-WARING CO., Philadelphia, Pa., in Bulletin 4-1401, with supplementary sheet 2, explains the recent development of Yarway balanced control valve in both angle and globe patterns, with several forms of operating mechanisms. This equipment was designed primarily for use in conjunction with Yarway Lea V-Notch recording meter, but is also used on heaters and tanks that need regulating equipment. Pamphlet DT-1601, which is entitled "Tight in Two Places," describes Yarway double tightening valves for use on acid lines, soot-blowing systems, for locomotive service and pneumatic systems in addition to boiler blow-off use. Copies will be sent to anyone interested, upon request.

BAKER & CO., INC., Newark, N. J., announces the publication of a booklet on platinum, which contains the historical summary of platinum, occurrence of platinum ore, the platinum metals and uses of platinum, its allied metals and alloys.

THE NASH ENGINEERING CO., South Norwalk, Conn., has issued two new bulletins, No. 16 describes and illustrates the Jennings hytor condensation motor-driven centrifugal pump, which is designed to handle condensate from steam-heating or drying systems. They may be used to handle any liquid which will not attack the pump interior. In Bulletin 17 the Jennings hytor air line vacuum heating pumps, electric motor drive, for use on air line vacuum heating system or any service requiring air to be exhausted under a vacuum not exceeding 20 in. of mercury are described and illustrated. The illustrations in both catalogs show the machinery in natural colors.

THE TITANIUM ALLOY MFG. CO., Niagara Falls, N. Y., in a leaflet announces the offering of the facilities of the Commercial Service Department of the physical, metallurgical and metallographic laboratories to manufacturers and others interested in metallurgical and mechanical lines.

THE RAILWAY & INDUSTRIAL ENGINEERING CO., Greensburg, Pa., is putting on the market a rocking cableway for handling materials which is described in a four-page booklet.

THE NEW ENGLAND TANK & TOWER CO., Everett, Mass., has issued a booklet, No. A-121, descriptive of a "Nett-Co." product, the direct-connected motor-driven agitator drive.

THE AJAX ELECTROTHERMIC CORP., Trenton, N. J., in a recently published circular treats the Ajax-Northrup high-frequency induction furnace as a laboratory tool, which is used for melting steel, brass, silver and other metals and for heat-treating, carbonizing, annealing, etc.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS will hold its thirty-eighth annual convention at the Washington Hotel, Washington, D. C., Oct. 24-26.

INDUSTRIAL COST ASSOCIATION will hold its second national conference at Pittsburgh, Pa., Nov. 2-4, with headquarters at the William Penn Hotel.

INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA will hold its annual convention at the Waldorf-Astoria, New York, Nov. 1-5.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS is holding its fall meeting at Springfield, Mass., Oct. 5 to 7.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

How May Research Be Fostered?

A PLEA for a restricted use of the word "research" was made in these columns not long ago, using as a basis DR. HYDE'S admirable outline of investigative work in science and engineering. Doubtless many who read those words agreed with DR. HYDE that the word "research," meaning a diligent and critical investigation in seeking facts or principles, clearly includes the five items in his classification, and would hold the editorial writer guilty of overdrawing a picture merely to emphasize his point of view. They would be inclined to use the word research as a generic term, modified by descriptive adjectives when necessary.

However that may be, undoubtedly all will agree that the unqualified word research or the phrase "pure scientific research" accurately describes patient searching in nature for evidences of hitherto unknown phenomena, and that such researches are of the utmost value in furnishing the fundamental basis of scientific and engineering progress. All will agree that too few qualified men are now engaged in such work, and the problem of instituting and stimulating research has been argued at length.

One result of this discussion is the conclusion that research ("pure scientific research," if you must, to be precise) can best be done in the future where it has always been done in the past: in universities or in endowed laboratories. Investigators in these institutions do not need to worry whether the things they are bringing to light can be capitalized immediately at a satisfactory profit. The highest type of university professor, as a matter of fact, is continually urged to extend the limits of his knowledge, not only because he must do so in order to fulfill his mission as an instructor, but because he realizes that his science is a growing thing, and he is the husbandman.

This urge from within is the researcher's motive power. Researches, in fact, cannot be directed. Imagine EUCLID examining his calendar after breakfast to find that this day he was to square the circle! Or that LIVINGSTON, in the trackless jungle, could be directed to discover Victoria Falls!

Undoubtedly, the researcher must be free! Various agencies which are now bestirring themselves to stimulate research would do well to bear this thought in mind. Acting on it they can do the most good. Perhaps they can see to it that the research professor receives a salary which will enable him to live without grinding economy in the dignified manner the importance of his work warrants, and permit him to visit freely at other institutions where interesting work is in progress. Relieve him of petty administrative detail. Then go away and leave him alone! For the true researcher has the same spirit as DAVY CROCKETT; he will move on as soon as he can see his neighbor's smoke.

Finding the Effect of American Valuation

MR. FORDNEY'S tariff has retired to the chambers of the Senate Finance Committee and the orders are that it is not to be disturbed—at least during the present session of Congress. Tariff problems have for the moment given way to discussions, discussions, discussions on taxation and unemployment. But we are reminded occasionally that the important policy of American valuation is still in abeyance, notwithstanding that it is the framework upon which the entire tariff must be built.

A few months ago a small group of prominent manufacturers met at the Chemists' Club of this city and organized the American Valuation Association, which has since been carrying on a vigorous campaign in favor of this change in our methods of assessing ad valorem duties. The press has been flooded with arguments and propaganda for its adoption and meetings of manufacturers have been held all over the country. In the meantime associations of importers, some of the large department stores and other tradesmen have been equally active in opposing the measure. It is obvious that this important issue must not be decided by either of these agencies nor by a Congress supplied only with partisan information obtained from these selfish sources.

American valuation of imports is generally referred to as an untried experiment, the effect of which can be studied only after the principle is adopted. We seem to lose sight of the fact that the true effect is susceptible of determination in advance. The importers' invoices in the Custom House and the manufacturers' sales records contain data which will show exactly what would have been the results had such a plan been in operation last week, last year or ten years ago.

Recognizing the good that such an investigation might accomplish, Congress recently placed a substantial appropriation at the joint disposal of the Treasury Department and the Tariff Commission and instructed these agencies to make an exhaustive study of American valuation. Formal announcement has not been made as to the complete plans for this co-operative work, but a director has been appointed and at least one conference has been held with manufacturers and representatives of the trade.

We had hoped that the investigation might be of a non-political nature and we were therefore surprised to learn that the directorship has been conferred on a former secretary of the Republican National Committee. However, he may have been selected for his appreciation of scientific tariff making, so we still believe the investigation can be made worth while. Information of unusual industrial significance can be obtained from a comprehensive study and a judicious sifting of facts and figures. American valuation holds much at stake for the chemical industry and we are justified in insisting that the plan be put to a thorough and impartial test.

Electrochemists At Lake Placid

ANIMATED discussion marked the technical sessions of the Lake Placid meeting of the American Electrochemical Society, a complete report of which will be found elsewhere in this issue. Organic electrochemistry was represented on the program by several papers, but the most interesting contributions to the subject came out in discussion following Mr. LIDBURY's assertion that the topic was of little or no practical importance. This brought several members to the defense with brief statements of what is being done industrially with organic electrochemistry. Unfortunately the speakers could not go into detail regarding their work, but enough was said to show that organic electrochemical industry is an accomplished fact in this country and that we can confidently look forward to further development and specific applications that will be made public in due time.

A valuable contribution was made to the old but ever new subject of corrosion by J. NEWTON FRIEND, whose theory, while not pretending to finality or completeness, aids in explaining some phenomena hitherto unexplained or but partly understood. In the symposium on electro-deposition Mr. BLUM's papers were of first importance, showing the influence of the crystal structure of the base metal on the nature of the deposit of the plated metal. Important conclusions were also presented on the effect of addition agents and their relation to current density. In the symposium on the electric furnace in non-ferrous metallurgy there was a natural, though not wholly unavoidable, tendency toward commercialism that should not encroach too far on the scientific and engineering aspects of the subject. A judicious mixture of papers by furnace users as well as by manufacturers will avoid giving such a program too much of the trade aspect. Mr. ST. JOHN'S paper can be commended as a fair and impartial exposition of the influence of different types of electric furnace on non-ferrous metallurgy.

The meeting was held amid delightful surroundings that offered opportunity for sport and recreation between technical sessions. Golf, mountain climbing and lake bathing for the hardy ones were among the daily diversions which added to the regular activities left few idle hours. Nor were indoor sports entirely lacking. The club menus printed in Mr. DEWEY's simpler spelling added zest to the game of deciphering the code in order to get enough to eat. Careful inquiry revealed no converts to the new orthography, and some were found who said that *apl py* and *cofi* didn't even taste like mother's justly famous brands.

Baltimore has been selected for the spring meeting and plans are already under consideration by energetic local members. The earlier convention of the American Institute of Chemical Engineers in the same city in December should in no way detract from the success of the electrochemical meeting. Industrial plants in ample number and variety will be open to inspection and the meeting will take on a character quite different from the last two, which have been held at resorts wholly lacking in industrial attractions. Each type of meeting place has its merits and demerits, and while some would always prefer the industrial city, we think the Society gains by occasionally selecting the pleasure resort. Much depends on the appropriateness of the technical program—a point that the directors are keeping in mind.

Railroad Rates And Business Activity

IT IS DOUBTFUL whether any really good purpose is served by the talk now so prevalent that recovery in business activity is prevented or at least greatly retarded because of the failure of railroads to reduce their freight rates. That shippers should discuss this matter with railroad officials is eminently proper, but talking to the general public is another thing altogether. The public has absolutely no voice in the matter. One may admit that it was representatives of the public who passed the transportation act, but the act more than justifies the present rates, for it authorized the Interstate Commerce Commission to set rates calculated to yield the railroads 6 per cent. Under the rates thus fixed the railroad earnings during the first six months of this year were at an average rate of 1.8 per cent a year, while in July the earnings were at the rate of 4.5 per cent. There is a large deficiency, and the commission cannot order reductions, which are feasible only by voluntary act of railroad officials.

We are not proposing that facts be concealed from the public, but when the public is told that failure to reduce rates is responsible for any prolongation of the business depression a one-sided view if not an entirely erroneous view is promoted. The public is not equally well informed as to the revenue needs of the railroads, in view of earnings reports through July, nor is it given adequate arguments that reductions in rates would greatly stimulate business.

For several months past much that has been printed and much that has been said in private conversation has been in emphasis of the bad features of the business situation, while the good features have been slurred over. A year ago it was being said that we needed harder and more efficient work, while today much is said of the men who are out of employment, some of them being idle because they refuse to accept reasonable wages, and practically nothing is said of the hard and efficient work of those who are in employment, although a fair count might show the latter to outnumber the former six or eight to one. If all who work, not simply those who are called artisans or common laborers, were reckoned with, the proportion would probably be eight or ten to one.

It is considered a debatable question whether majorities are always wrong or only usually wrong. It is a fairly safe working rule that if a remedy for a state of affairs is generally urged it is a false remedy. As suggesting the correctness of this statement one can recall various periods before the war when the talk throughout business circles was that the Interstate Commerce Commission should permit the railroads to advance freight rates so that the railroads would buy things and make business good. Now many men—and quite possibly the same men—want rates reduced even though the railroads have not been making their bare expenses.

There is one subject, on the other hand, in which publicity would do a great deal of good, and that is the matter of wage rates and working conditions in the building trades. Some of their peculiar doings have been aired, but the subject will stand much more publicity, and such publicity would be a vastly greater help toward improving business and industrial conditions than saying to the public that it cannot expect improvement in business until by some chance freight rates are reduced.

And Now the Question:

"What Is the Chemical Engineer?"

THAT puzzling enigma, What is a chemist? remains unanswered, but in the meantime some badly needed light is being shed on the more complex problem of defining the status of the chemical engineer. Dr. BAEKELAND in his recent address before the International Meeting of the chemical societies stressed the importance of bringing the public to a complete realization of the duties of both the chemist and the chemical engineer and of their contribution to our modern civilization. In referring to the confusion existing in the mind of the layman, he declared: "What appears even less obvious is the relation of the chemist to the chemical engineer. It is less known that a man may be a scientific star of the first caliber and yet incapable of utilizing his science in the industries or of applying it in the many other ramifications of the economics of our civilization."

We believe that one of the reasons for the lack of a definite understanding of the functions of the chemical engineer is the failure of some of our colleges and universities to recognize chemical engineering as a branch of the engineering profession. They do not place the subject on a parity with civil, mechanical and electrical engineering, but relegate it to a position of little importance either by lumping it in with their chemistry courses or otherwise hiding it away in their colleges of arts or sciences. Only a few of the more forward-looking institutions have completely divorced their curricula in chemistry and chemical engineering and have wisely placed the latter courses in their engineering colleges. In the survey of chemical engineering education made by a committee of the American Institute of Chemical Engineers and summarized in our issue of June 15, the reader was impressed by the wide variance of opinion as to what constitutes chemical engineering. This was evidenced by the fact that in the seventy-eight institutions considered at that time about 225 different studies were being taught to chemical engineering students and in no two institutions were the chemical engineering courses identical or even substantially alike. Permitting a certain amount of specializing is undoubtedly a wise policy, and the student, under proper supervision and within reasonable limits, should be allowed to choose his own line of development. It is obvious, though, that much standardizing in our chemical engineering education is necessary, and this can best be promoted by a definite knowledge of what is required of the chemical engineer and in what fields his energies are to be expended. The failure to equip the graduate with sufficient knowledge to cope with engineering problems or the overdevelopment of the engineering viewpoint without a thorough grounding in the fundamentals of chemistry are mistakes which some of our institutions have made and are continuing to make. It is not out of place, therefore, to weigh carefully the words of one who has been successful in the thoroughly practical phases of chemical engineering. We continue to quote from Dr. BAEKELAND'S address: "The chemist, confined by the walls of his classroom, his laboratory or his library, sometimes fails to exercise sufficiently his sense of proportion. He is inclined to concentrate too much on only the part of the subject with which he is confronted. He is apt to neglect other considerations, which, although unimportant from a scientific viewpoint, frequently carry with them the very elements of success or failure in practical applica-

tions. Nor are the engineers, as a class, free from being carried away by a one-sided point of view, although it is admitted that their way of grappling with a problem is more along quantitative considerations. The ways of thinking and acting of the chemist and of the chemical engineer are often along decidedly different points of view, yet if these can be compromised, or harmonized, they bring forth good engineering."

Unemployment

Among Engineers

CURIOSLY enough, one overoptimistic person expressed the view at the President's conference that there was no unusual amount of unemployment at the present time. How fortunate it would be if a meeting called to find work for idle hands to do should discover its job already done, simply because there was no idleness!

Engineers, members of what is now a "feast or famine" profession, generally would agree with the more pessimistic view—that jobs are few and far between. Chemists and metallurgists particularly have been through lean months. Many large firms have been slashing right and left into their appropriations for investigative work, forgetting their war-time experiences, when they clamored for competent technical men to show them how to produce an acceptable article. Some have even gone so far as to curtail their expenditures for publicity.

It is all very well for the detached philosopher to remark, "Oh, very well, executives who regard research as a luxury would not profit by the findings of their laboratory anyway." But true though that may be, it does not make it any easier for the idle technical man to locate new work worthy of his talents, or comfort the engineer who is earning bread and butter as an analyst or a "man at the fire."

As we see it, the big problem of seasonal employment of engineers will not be solved until the public realizes that the increasing vigilance of engineering control is necessary in order that any manufactured product can reach the ultimate consumer with the greatest perfection and the least waste en route—that is to say, until the people of the United States know that the engineer is essential to a quality product at a reasonable price.

From this standpoint it is apparent that some time will elapse before the engineer will come into his own, and many faint-hearted and unfit will take an easier way. But this is his undoubted destiny, and the rewards to the strong will be great.

Many agencies are hastening the day of public appreciation of the engineer: The Federated American Engineering Societies has its greatest opportunity for usefulness in this very direction; the technical press has never been more influential nor more representative of the dignified calling of its subscribers; but first and foremost, the individual engineer is and must be the most powerful exponent of his own worth. No matter how hard hit he may be by the present industrial depression, he can show his neighbors and employers that he is by a wide margin a better man than another of no technical or scientific training. Such a man, of course, is a good citizen and lends his aid in every movement to improve living conditions and uphold the ideals of our Government. Such a man, perhaps needs no admonition of ours, but in view of the many signs that the trough of depression has passed, he may be heartened to the long pull ahead by a cheery "God speed."

LAKE PLACID IN THE ADIRONDACKS, NEW YORK

Meeting of the American Electrochemical Society

Report of the Fortieth General Meeting Sept. 29 to Oct. 1, 1921—Papers on Corrosion and Electrolysis—Symposiums on Non-Ferrous Metallurgy and Electrodeposition—Meeting of the Board of Directors—Social Features

THE fortieth general meeting of the American Electrochemical Society was held Sept. 29 to Oct. 1, 1921, at the Lake Placid Club in the Adirondacks. Largely due to the untiring efforts of President Smith and William M. Corse the meeting was one of the most enjoyable and sociable ever held by the society. Seldom in the history of the society has there been such an opportunity for the forming and cementing of friendships. The beautiful surroundings and exhilarating air put every one in the best of moods and was conducive to sparkling wit and joyous laughter. Never before were so many electrochemists' wives in evidence.

The three mornings were devoted to the reading and discussion of papers. President Acheson Smith presided. On Thursday the two general themes introduced were corrosion and electrolysis; on Friday the symposium on non-ferrous electrometallurgy was held, and on Saturday the symposium on electrodeposition.

Papers on Corrosion

ALKALINE AND ALKALINE EARTH METALS IN CONNECTION WITH NON-FERROUS ALLOYS

The first paper of the Thursday, Sept. 29, session was by Charles Wickers of Buffalo on "Experiences With Alkaline and Alkaline Earth Metals in Connection With Non-Ferrous Alloys." The author reported on a number of experiments which tended to show that metallic sodium could not be used satisfactorily for deoxidizing copper but that when added to molten copper or bronze in the form of an alloy such as sodium-tin, it appears to produce an alloy of superior torsional strength. Of the alkaline earth metals, calcium is valueless in producing solid copper castings, nor has it any value in bronze. As a deoxidizing agent in copper,

calcium is at its best when combined with an acid element such as silicon, and this combination is improved by a third element. This latter combination is being used with success for the production of copper castings possessing very high electrical conductivity. Barium and strontium appear slightly more promising than calcium, but he stated that a large amount of foundry research work is necessary before their actual value is known.

This paper was of particular interest to the electrical engineers present and it was pointed out by C. G. Schluederberg of the Westinghouse company and John A. Seede of the General Electric Co. that high electrical conductivity was absolutely essential if the copper castings were to be used in electrical apparatus. It was suggested that castings deoxidized by Vickers' new alloy be compared with Weintraub's castings purified by boron suboxide. Colin G. Fink of South Yonkers emphasized the importance, when selecting a deoxidizer for copper, of taking into account the melting points of the products formed. If calcium is used, the calcium compounds resulting must preferably be fluid and readily rise to the surface of the molten copper. Prof. Joseph W. Richards added that it was equally important to have the product agglomerate rapidly.

ELECTROLYTICALLY PRODUCED CALCIUM-BARIUM-LEAD ALLOYS COMPRISING FRARY METAL

William A. Cowan, L. D. Simpkins and G. O. Hiers contributed a paper on "Electrolytically Produced Calcium-Barium-Lead Alloys Comprising Frary Metal." They gave a detailed account of their study made at the research laboratories of the National Lead Co. on the development of Frary metal and of its production by electrodeposition from a low melting point mixture of cal-

cium and barium chlorides over a bath of molten lead as cathode.¹

In the discussion, Charles H. Proctor of the Roessler & Hasslacher Chemical Co. referred to his experience in recasting 12 per cent antimonial lead and the difficulty of preventing dross from segregating in spots. Would the addition of small percentages of Frary metal to the melt eliminate or reduce this evil? Would it be better than the use of the green hickory poles? Prof. Richards called attention to the very low efficiency of the Frary metal cells or pots operating at 2,000 amperes and 10 volts.

ELECTROLYTIC CORROSION OF THALLIUM-LEAD ALLOYS

Tests made on a series of lead alloys were outlined in a paper on "Electrolytic Corrosion of Thallium-Lead Alloys" by Colin G. Fink and Charles H. Eldridge of South Yonkers. The alloys were cast into anodes and submitted to electrolytic corrosion in an acid copper sulphate electrolyte containing both hydrochloric and nitric acids. Thallium is one of the few metals whose lower oxide is more stable than the higher oxide; another distinctive feature of thallium is that when alloyed with lead the fusion curve rises decidedly above that of either constituent, whereas the melting point of most other binary lead alloys is lower than that of at least one of the constituents. A minimum anodic corrosion loss of 1.2 lb. per 100 lb. of copper deposited resulted with a lead anode containing 10 per cent Tl and 20 per cent Sn,² as compared with 65 lb. loss for ordinary lead. In general it was found that lead alloys with high melting points are more resistant to corrosion. The low corrosion losses are largely due to a very adherent protective film formed during electrolysis.

Discussing the thallium-lead alloys, Henry Howard of Cleveland referred to the possible substitution of one or the other of these for ordinary lead in the construction of sulphuric acid chambers. George B. Hogaboom of the Scovill Manufacturing Co. called attention to the need of a high melting point solder that would withstand enameling oven temperatures. In reply, it was stated that lead-thallium alloys readily dissolve copper and silver and it would therefore seem that a lead-thallium or a lead-thallium-tin alloy would answer the high-temperature requirements.

A NEW THEORY OF THE CORROSION OF IRON

Dr. J. Newton Friend of Birmingham, England, has made an exhaustive study of the corrosion of commercially pure iron, as a result of which he has developed an entirely new interpretation of the mechanism of corrosion. According to this theory, iron in coming into contact with liquid water in the presence of air or oxygen slowly oxidizes to ferrous hydroxide. This, however, is produced in the colloidal condition—a state in which it is usual for many substances to be particularly reactive. The ferrous hydroxide hydrosol now undergoes oxidation to a higher hydroxide hydrosol, ferric hydroxide sol being produced in the most favorable circumstances. This higher hydrosol is now alternately reduced in contact with the iron and oxidized again by atmospheric oxygen, thus catalytically accelerating the oxidation of the metal. When the sol flocculates or

precipitates out, it yields rust. If this theory is correct, it will be clear that all processes, whether physical or chemical, which effect the precipitation of positive colloids should tend to retard corrosion, and, on the other hand, those which tend toward the stabilization of positive colloids will enhance corrosion. These conclusions have been substantiated by the results of numerous experiments.

The paper was discussed at length by Dr. Fink; in concluding his remarks he suggested that Friend's theory ought to be borne in mind when studying the corrosion of metals other than iron. W. E. Hughes in writing from London referred to a recent experimental confirmation of Friend's theory by A. Ackermann.³ Ackermann observed under the microscope the formation of ferric hydroxide and that this colloidal substance is the first product of a series of reactions which finally result in rust. Hughes closes his letter with the remark that the fundamental problem, however, is still unsolved, since Dr. Friend does not tell us what the forces are that operate to cause the conjunction of the iron atoms and hydroxyl groups of which the hydrosol is composed. "What forces operate to produce the colloid? In the answer to this question lies the statement of the cause of the corrosion of iron."

RUST PREVENTION BY SLUSHING

The practical side of the problem of the corrosion of iron was emphasized in the paper on "Rust Prevention by Slushing," presented by Dr. Haakon Styri. He described the results of a series of investigations made under his direction at the S.K.F. research laboratory in Philadelphia. The conclusion arrived at was that a prerequisite for protection against rust by greases is a thorough cleaning of the steel parts by an aqueous solution, preferably by an oil emulsion which leaves a thin oil film for short time protection. Such oil emulsion is also a very good grinding liquid. It protects from rust and gives a fine finish.

Dr. Styri's paper was discussed by President Acheson Smith, Charles Proctor and others. Dr. William Blum of the Bureau of Standards said that the Government has difficulties in preventing the corrosion of various munitions in storage, but has found that simple slushing compounds would satisfactorily combat corrosion. Prof. Richards referred to a Japanese sword in his possession which had been slushed with oil containing very finely divided lead. After years of exposure there is no visible corrosion.

Papers on Electrolysis

TRANSFORMER OIL SLUDGE

Three general types of transformer oil sludges were discussed by C. J. Rodman of the Westinghouse Research Laboratories. The first, or asphaltic, sludge is produced by the oxidizing action on poor transformer oils such as contain unsaturated compounds, water, small resinous bodies and certain accelerators or catalysts. Examination of the sludge showed that it consisted largely of hydrocarbons of high molecular weight containing oxygen. Thus it may be considered as a combination of oxyasphaltic compounds. It is the most general form of sludge. It collects upon the active parts of the transformer, thus preventing the dissipation of heat. If moisture-free its electrical properties are fairly good. The second type, or soap sludge, is a good

¹This paper will be printed in a subsequent issue of CHEMICAL & METALLURGICAL ENGINEERING.

²U. S. Pat. 1,384,056, July 12, 1921, CHEM. & MET. ENG., vol. 25, No. 14, p. 668, Oct. 5, 1921.

³Kolloid Z., vol. 28, p. 270 (1921).

moisture and oxygen carrier. It forms slowly and it is difficult to remove entirely by filtration. The third type, or the carbon sludge, is due to electrical breakdown.

Commenting on Mr. Rodman's paper, W. S. Moody of Schenectady described a series of tests carried out at the General Electric plant which led to the conclusion that when the oil was exposed to air there was much sludging and in the absence of air there was practically none. Accordingly an auxiliary tank was connected to the transformers and all air excluded.

ELECTROLYSIS OF ORGANIC COMPOUNDS

Dr. Raymond Freas, of New Orleans, submitted a paper on "Factors Influencing the Electrolysis of Organic Compounds," in which he discussed the factors entering into electrolytic reduction and described a convenient experimental arrangement used in their study.

Dr. C. J. Thatcher of New York, who has been manufacturing large quantities of organic chemicals electrolytically for a number of years, called attention to the interesting fact that the product could be varied by changing the charge of the electrode from negative to positive or *vice versa*.

ELECTROLYTIC DISSOCIATION OF CYANAMIDE AND OF SOME OF ITS SALTS IN AQUEOUS SOLUTIONS

Prof. Naoto Kameyama of the Tokyo Imperial University forwarded a manuscript on "The Electrolytic Dissociation of Cyanamide and of Some of Its Salts in Aqueous Solutions." He found that sodium acid cyanamide in aqueous solutions is hydrolyzed at 25 deg. C. to the extent of 4.5 to 12.9 per cent in the dilutions of 10 to 80 liters per gram mol, respectively. If this hydrolysis is prevented by an excess of cyanamide, dissociation occurs to almost the same extent as in the case of sodium formate. Under similar conditions unhydrolyzed calcium acid cyanamide dissociates to the same extent as magnesium formate or calcium nitrate. The primary dissociation constant of cyanamide, as an acid, at 25 deg. C., was found to be 5.42×10^{-11} ; the conductivity of the cyanamide anion being 54.4 at 25 deg. C.

ELECTROLYTIC OXIDATION OF THE LEUCO-BASE OF MALACHITE GREEN

Alexander Lowy and Elmer H. Haux gave an account of their experiments carried out at the University of Pittsburgh on "The Electrolytic Oxidation of the Leuco-Base of Malachite Green." They stated that it is usually oxidized on a commercial scale by a slight excess of the theoretical quantity of lead peroxide, which must be carefully prepared, and used in the form of a thin aqueous paste. The insoluble lead compounds are then filtered, the filtrate heated and the soluble lead salts precipitated with sodium sulphate. In order to ascertain the possibility of substituting electrical energy for chemical energy, forty-four experiments were carried out by the authors. The conclusions arrived at indicate the necessity of a catalyst, an elevated temperature for efficient oxidation, a low concentration of the leuco-base in the anolyte, and sulphuric acid as solvent and electrolyte. The highest dye yield was obtained with uranyl sulphate as catalyst, platinum cathode, and nichrome gauze anode in dilute sulphuric acid solution, at a temperature of 85 deg. C.

A very animated discussion ensued in which Messrs. Burwell, Lidbury, Thatcher, Fink, Howe and Lowy participated. Dr. Arthur W. Burwell of Chagrin Falls, Ohio, announced that the Reliance Aniline & Chemical

Co. at Poughkeepsie was producing commercially hydroquinone directly from benzene by electrochemical methods. He stated furthermore that the Western Reserve Chemical Co. of Cleveland had been making tons of phthallic anhydride for the past four years. Dr. Lowy added that since writing his paper new results have been obtained: The yield of malachite green has been as high as 67 per cent, as compared with 60 per cent by the older processes. He displayed samples of yarns that had been dyed by the "electric malachite" and had been tested at the du Pont laboratories. The color yield was up to 100 per cent strength; the solubility as good as that of ordinary malachite, in some cases even better. Experiments are now in progress on the electrolytic oxidation of dimethylaniline to dimethyl violet.

ELECTROLYTIC PRODUCTION OF SODIUM PERBORATE

Peder Chr. Alsgaard presented a paper on the "Electrolytic Production of Sodium Perborate," in which he embodied the results of his work at Cornell University. The chemical properties and industrial uses of sodium perborate were reviewed and a detailed account was given of the research work by Arndt and Valeur on its preparation by the electrolysis of a borax solution containing sodium carbonate. In order to develop the technical and commercial utilization of the electrolytic process, the experiments of Valeur were repeated on a large scale, and although certain difficulties were encountered, practically all of the earlier results were confirmed. From these experiments it was possible to furnish the facts and figures necessary for the technical design and calculation of the costs of production.

Commenting on Mr. Alsgaard's results, Prof. Richards reported that he had visited the electrochemical plant at Fredriksstad, Norway, this past summer and witnessed the introduction of the new Moltkehansen perborate process. Mr. Alsgaard added that in this new process cyanide is used to prevent reduction of perborate by iron. Dr. F. A. Lidbury of Niagara Falls emphasized the importance of keeping the concentration of iron low in order to get good yields.

THE ELECTROLYTIC OXIDATION OF HYDROCHLORIC ACID TO PERCHLORIC ACID

Prof. H. M. Goodwin and Dr. E. C. Walker, 3rd, of the Massachusetts Institute of Technology have presented the results of their investigations on the best conditions under which hydrochloric acid may be electrolytically oxidized to perchloric acid. They studied the effect of concentration of acid, current density, duration of electrolysis and temperature of the yield.¹

GRAPHIC CONTROL OF ELECTROLYTIC PROCESSES

B. G. Worth of New York outlined briefly his method of "Graphic Control of Electrolytic Processes." It was found by research in a chlorate plant that the high yields for the particular type of cell, electrodes and other chemical and electrical features depended principally on the varying relations among three factors: two chemical factors which may be called *A* and *B* (representing concentrations of two compounds in question) and the third factor, the temperature, called *T*. It was calculated from the reactions that in order to get the best results a certain numerical relation must exist between *A* and *B*. *A* was incapable of direct control, being the result of establishment of equilibrium, but *B*

¹The paper will be printed in full in a subsequent issue of this magazine.

was controllable by addition agents. Knowing *A*, it was possible to compute what *B* should be, which figure was called "Proper *B*" (*PB*). Accordingly a system was inaugurated by which the contents of each cell were analyzed daily and the results plotted by weeks. From the curves it was obvious that whenever the *B* advanced or receded beyond a certain point remedial measures had to be taken. In practice this was a simple matter, as it necessitated only a change in the rate of feeding addition agents. After a while it became possible to anticipate changes by extending the curve by extrapolation and then making proper changes 24 hours in advance, thereby forestalling what otherwise would have been a falling-off of efficiency.

Mr. Worth's paper was discussed by Dr. Schluederberg of Pittsburgh. He commented favorably upon the method and added that it is of particular value to the young electrochemist entering the employ of one of our large factories and desiring to familiarize himself with details in plant operation.

PROF. RICHARDS' TALK ON SCANDINAVIA

At the conclusion of the Thursday morning session Prof. Richards gave a very enjoyable talk on his recent experiences in Scandinavia and reported that the Söderberg electrode is rapidly displacing the older types. In Norway at one of the metallurgical plants the Söderberg is carrying 1,000 amp. At an electric steel plant a tilting Heroult furnace is equipped with Söderbergs which are fed in sections 2 m. long. There are no additional complications as compared with the older types of electrode. The capacity of the Heroult is 6 tons and the distance between metal and roof is about 1 meter. At another plant large aluminum-cased Söderbergs up to 18 in. square were just being tried out on the aluminum cells. The consumption of the electrode in the bauxite bath was very uniform, the ends of the electrodes remaining plane parallel.

Symposium on Non-Ferrous Electrometallurgy

INFLUENCE OF THE ELECTRIC FURNACE ON THE METALLURGY OF NON-FERROUS METALS

The opening paper of the symposium was "The Influence of the Electric Furnace on the Metallurgy of Non-Ferrous Metals," presented by H. M. St. John of the Detroit Electric Furnace Co., in which he gave a general review of the changes which the electric furnace is making in the non-ferrous metallurgical practice and showed that by using electric melting, products of higher quality are produced with less labor and wastage than when using fuel-fired furnaces.

The paper was enthusiastically received and a very lively discussion followed in which both furnace builders and furnace users participated.

RESISTANCE TYPE ELECTRIC FURNACE

T. F. Baily presented a paper on "The Resistance Type Electric Furnace in the Melting of Brass and Other Non-Ferrous Metals." He enumerated the points to be considered in the selection of an electric furnace and is of the opinion that, when taking into consideration the total cost per ton of merchantable castings or bars produced and the adaptability over a wide range of alloys, the resistance type of furnace comes more nearly filling all the requirements than any other type of furnaces.

H. M. St. John and H. W. Gillett of Ithaca, N. Y., took exception to some of the claims made by Baily.

John A. Seede of Schenectady advocated a more general application of electrode regulators. Dr. Fink referred to the melting of copper in the Baily furnace and Dr. Richards brought up the question whether the color of the metal had any effect on the speed with which the melting temperature is attained in a furnace where the heat is indirectly applied. St. John and Gillett maintained that at high temperatures the color of the metal has no effect on thermal efficiency. At low temperatures, however, as Mr. Seede reported, it was found that aluminum absorbed heat 7 per cent as fast as copper. Mr. Baily added that temperatures up to 1,850 deg. C. are practical in his furnace and that he had successfully melted 0.05 carbon steel.

ELECTRIC VS. FUEL-FIRED FURNACE PRACTICE

N. K. B. Patch of the Lumen Bearing Co. in his paper, "Comparison of Electric Furnace Practice With Fuel-Fired Furnace Practice," related his experiences with a Baily and a Detroit Rocking furnace as compared with fuel-fired furnaces. The outstanding advantage of the electric furnace is its cleanliness and comfortable working conditions. On the other hand, a fuel-fired furnace still has a decided advantage over the electric furnace in the consideration of first cost.

Mr. Patch's paper was commented upon by Messrs. Gillett, Richards, Howard, Lidbury and others. C. B. Gibson of Pittsburgh and George K. Elliott of Cincinnati contended that it was almost impossible to draw cost comparisons, the prices for fuel and electric power varying in different localities. Dr. Richards mentioned that during a recent visit to the Lumen Bearing Co.'s plant he noted with much satisfaction that the outside of the furnaces had been painted white. According to his experience, this bright outer surface increases the thermal efficiency by 10 per cent.

MODERN DEVELOPMENTS IN THE BRITISH BRASS INDUSTRY

Ernest A. Smith of the British Non-Ferrous Metals Research Association submitted a detailed exposition on the "Modern Developments in the British Brass Industry." There appears to be comparatively little scope in Great Britain for electric furnaces of large capacity such as the Ajax-Wyatt, Detroit Rocking, and the Baily, in which the bulk of the electric brass melting is done in America. These furnaces require large and expensive installation and must be operated continuously on one or at most two standard alloys before any material saving can be shown. These conditions do not apply to a large majority of the British works, many of which have only an average daily output of from 500 to 600 lb.

ELECTRIC SILVER SMELTING

One of the most interesting papers of the symposium and one which included a number of novel features was the paper by H. A. DeFries of New York on "Electric Silver Melting." Silver melting in the electric furnace eliminates high crucible cost and the necessity of an experienced melter, which are essential to gas- or oil-fired crucible practice. Distinction is made between pouring temperatures of bar silver (1,038 to 1,093 deg. C.) and of rolling mill and casting silver (1,293 to 1,304 deg. C.), when casting horizontal molds.⁵

Mr. DeFries' paper gave rise to lengthy discussions.

⁵For a description of the operating conditions for melting fine and sterling silver, melting outfit arrangement, cost and a comparison of the qualities of electric and crucible silver see *CHEM. & MET. ENG.*, Sept. 14, 1921, p. 507.

Mr. Hogaboom emphasized the importance of a high pouring temperature which can be so readily attained in the case of the electric furnace. Dr. E. F. Northrup of Trenton reported that over a million ounces of silver had been melted in his furnaces. In order to eliminate holes and flaws in the rolled sheets he has found it good practice to transfer the crucible from the electric furnace to an oil-fired furnace and permit the melt to soak for a time. Such metal when cast and rolled was free from flaws. In commenting upon the use of the iron block in the molten silver Dr. Fink said that after a number of heats the surface of the block showed very characteristic erosion marks, which would seem to prove that chemical reaction was taking place.^o

ELECTRIC MELTING OF NICKEL SILVER

Prof. F. C. Thompson of Sheffield University, England, communicated a brief note on his experience on "The Electric Furnace Melting of Nickel Silver." The author's opinion is that the arc furnace is satisfactory only where all the constituents of the melt are non-volatile. When dealing with nickel silver this type of furnace ceases to be very useful as a result of the large volatilization of zinc around the electrodes. Experiments carried out in a small Kjellin induction furnace have not yielded results which possess much promise. Resistance furnaces would appear to be satisfactory. He then discussed the advantages of the use of such furnaces from the purely technical point of view—namely, reduction of the loss in zinc to less than 1 per cent, the occlusion of gases is minimized and a tougher alloy results owing to less carburization. He concluded by stating that where local conditions render it economically advisable the electric furnace of the external heating type possesses technical advantages, especially where large quantities of scrap require to be remelted.

Mr. St. John took exception to Prof. Thompson's conclusion that the resistance type of electric furnace is the only possibility for nickel silver, since he had confined himself to stationary furnaces.

ALUMINUM-COPPER ALLOYS

Robert J. Anderson, of the U. S. Bureau of Mines, contributed a paper on "Aluminum-Copper Alloys," which constitutes an exhaustive treatise on the manufacture, properties and uses of the commercial aluminum-copper alloys employed in the United States. The classification of these alloys is shown in Table I. When dealing with their corrosion he stated that the question of the corrosion of the light aluminum-copper alloys under various conditions of service has not yet been thoroughly investigated, although numerous isolated

tests of particular compositions have been made under many conditions, and that it would be of the greatest interest to obtain data with regard to the effect of various additive elements, in small percentages, upon the corrosion of the usual light aluminum-copper alloys.

ELECTRIC FURNACES OF THE MUFFLED ARC TYPE

H. A. Winne of the General Electric Co. presented a paper on "Recent Developments in Electric Furnaces of the Muffled Arc Type." A number of new types of muffled arc furnaces for melting brass, bronze and similar non-ferrous alloys and metals were described. The larger rectangular shell type furnace was compared with new designs for smaller units having capacities of 1,500 lb. or less per hour. Among the many advantages claimed for the muffled arc furnaces described by the author are that little space for heating elements is required, metal losses by volatilization are reduced, a neutral or reducing atmosphere is maintained, and load fluctuations are small. They are adaptable to intermittent operation; other features are accessibility of hearth, low electrode consumption and small expense of refractories.

REFRACTORIES FOR ELECTRIC FURNACES

The increasing importance in selecting the right refractories for electric furnaces was brought out in the following two papers:

Electric Furnace Purification of Zirkite.—J. C. Thompson of Cornell University reported the preliminary results of his investigation on the possibilities of electric furnace purification of zirkite. He found that 90 to 95 per cent of the silicon may be largely removed from siliceous zirkite ore by heating a mixture of ore and carbon to above 2,220 deg. C. in an electric furnace. The best results appear to be obtained by feeding into an arc furnace a mixture of ore and coke, the amount of carbon being approximately that required to transform only the silicon to the carbide. The existence of stable double carbides of silicon and zirconium or of solutions of silicon carbide in solid zirconium carbide is suggested as an explanation of the incomplete removal of silicon when carbon in excess of that required to form only silicon carbide is used. Zirconia sufficiently pure for refractory purposes might be obtained from zirkite ore by removing the silicon in an electric furnace and following this by treatment with chlorine or phosgene to remove the iron. In conclusion Dr. Thompson discussed the refractory properties of zirconium carbide and the factors which limit its use.

In commenting on Dr. Thompson's findings, Frank J. Tone of the Carborundum Co. suggested using an excess of iron to remove all of the silicon in the zirkite. The small amount of ferrosilicon formed during the reaction might be removed magnetically. Gillett doubted very much whether such magnetic separation were at all possible; according to his experience it was impracticable. Fink pointed out that part of the iron would be tied up as ferrozirconium. As compared with magnesium oxide or thorium oxide, zirconium oxide is readily reduced at high temperatures. L. E. Saunders of the Norton Co. suggested that Dr. Thompson check his analytical results and try out his ideas on a comparatively large scale, since his present small-scale results are somewhat misleading.

Physical Characteristics of Specialized Refractories.—M. L. Hartmann and W. A. Koehler presented the results of their work at the Carborundum Research Laboratories on the cross breaking strength of special-

ized refractories. The average data are given in Table II.

TABLE II. SUMMARY OF AVERAGE CROSS BREAKING STRENGTHS

	Modulus of Rupture		Ratio	R at 1,350° C. R at 20° C.
	Lb. per Sq. In. 20 deg. C.	Lb. per Sq. In. 1,350 deg. C.		
Recrystallized carborundum (Refrax).....	2,312	2,437	1.05	
Bonded carborundum (Carbofrax A).....	2,103	2,274	1.08	
Bonded carborundum (Carbofrax B).....	2,651	2,129	0.805	
Bonded carborundum (Carbofrax C).....	2,215	1,918	0.866	
Silica No. 1.....	608	145	0.228	
Silica No. 2.....	491	178	0.363	
Magnesia.....	1,388	136	0.098	
Fireclay.....	665	113	0.170	
Bauxite.....	1,315	99	0.075	
Chrome.....	1,392	22	0.014	

Discussing the paper, Mr. Saunders warned against basing conclusions on but a few observations. For example, there are clays that have a decidedly higher modulus of rupture than that reported by Messrs. Hartmann and Koehler. Replying to Dr. Richards, Mr. Tone said that one of the large zinc smelters is using carborundum retorts and that these have been found entirely satisfactory.

AN ELECTRIC STEAM GENERATOR FOR LOW VOLTAGE

The first paper of the Saturday, Oct. 1, session was entitled "An Electric Steam Generator for Low Voltage," by F. A. Lidbury and F. A. Samps. The authors described a 250-kw. capacity electric steam-generating unit of the water-resistance type designed primarily for operation at 100 volts, but which could be used without much modification up to 500 volts.

In commenting on his own paper Dr. Lidbury called attention to the lamentable lack of reliable data on the conductivity of electrolytes at temperatures of 100 deg. and above. Frederick T. Kaelin of the Shawinigan Water & Power Co. described the electric steam generator in his plant.

Symposium on Electrodeposition

EFFECT OF PRESSURE ON OVERVOLTAGE

Prof. H. M. Goodwin and Dr. L. A. Wilson of the Massachusetts Institute of Technology presented a paper on "The Effect of Pressure on Overvoltage." Experiments were described in which the overvoltage of hydrogen against copper, nickel and mercury electrodes was determined under pressure varying from one atmosphere to a few centimeters of mercury. The values were determined by the bubble method, at room temperature, under conditions of very low current density, after a state of constant polarization had been established. The results in all three cases showed a rapid decrease at low pressures, confirming the hypothesis recently advanced by MacInnes and Adler to explain overvoltage phenomena.

RESEARCHES ON THE ELECTRODEPOSITION OF IRON

W. E. Hughes of London in his paper on "Researches on the Electrodeposition of Iron" presented the results of the work conducted by many investigators in this field, together with remarks and comments based upon his own experience. The different baths are classified as sulphate solutions, chloride solutions, and sulphate-chloride solutions. He then discussed various researches upon other solutions.

A very lively discussion followed. W. E. Ruder of Schenectady told of his studies of the magnetic properties of electrolytic iron. Dr. Fink referred to the use of electrolytic iron in place of Swedish iron and the

increasing difficulty of obtaining a clean scrap on account of the large quantities of alloy iron (copper, nickel, etc.) in use today. Dr. Blum of the Bureau of Standards discussed the cost item and reported that at present nickel plating is cheaper and more serviceable than iron or steel plating. Bradley Stoughton called attention to the large commercial electrolytic iron plants in France making boiler tubes. The product analyzes 99.97 per cent Fe and is as malleable as pure copper, due partly to the very low carbon content (0.008 per cent C.). He also commented on the large-scale tests of leaching sulphide iron ores with ferric chloride and then depositing out the iron electrolytically. The ferrous chloride is oxidized back to ferric chloride, and this is used in leaching fresh batches of ore. The product analyzes 99.99 per cent Fe. Henry Howard and A. W. Burwell questioned the practicability of the process. F. A. Lidbury surmised that there would be serious anode troubles with a highly corrosive liquor such as ferrous-ferric chloride. G. W. Elmen believed that the chief interest in electrolytic iron was in connection with the use of iron for magnetic purposes, even though Mr. Ruder seemed to think otherwise.

ELECTROLYTIC SOLUTION AND DEPOSITION OF COPPER

Prof. Thomas Roland Briggs of Cornell University presented in his paper on "Electrolytic Solution and Deposition of Copper" the results of his thorough and painstaking research on this subject. He has arrived at conclusions contrary to the general views held by Luther, Foerster, Addicks, Aldrich, Witherell and others and found that the electrolytic behavior of copper in solutions containing copper ions may be accounted for by means of two electrochemical processes: (1) The change from copper to cuprous ion or the reverse; and (2) the change from cuprous to cupric ion or the reverse. When copper dissolves electrolytically at the anode, cuprous ions are formed first. Similarly, at the cathode, copper can be deposited only by the discharge of cuprous ions. The cuprous ions formed at the anode may be removed either by electrolytic oxidation or by chemical means, depending upon conditions. If the removal of cuprous ions is entirely electrolytic, copper dissolves as bivalent metal. If removal is entirely chemical, copper dissolves as univalent metal. If at the cathode cuprous ions are supplied entirely by electrolytic reduction, copper is deposited as bivalent metal. If cuprous ions are supplied entirely by chemical means, copper is deposited as univalent metal. This theory has been successfully applied to the electrolytic behavior of copper in cyanide, chloride and sulphate electrolytes. The theory is a general one and can be adapted to metals other than copper.

Briggs' paper was discussed by Messrs. Fink and Blum, who emphasized the importance of having a good working hypothesis, such as that of Briggs, in conducting researches in electrolytic refining or electroplating.

ELECTROMETALLURGY OF ZINC

W. R. Ingalls, in his paper on the "Electrometallurgy of Zinc," referred to the plants at Great Falls, Trail and Risdon. Under favorable conditions zinc can be produced electrolytically at these plants on terms as low as to permit it to meet any competition. The limitations of the process are that it must be conducted on a large scale and the cost per unit of capacity is greater than that of the ordinary distillation plant. The electrothermic process has been successfully practiced in Scandinavia, especially at Trollhattan in Sweden and Sarps-

borg in Norway. The electrolytic process produces a high-grade zinc at less cost per ton of ore than in the electrothermic method.

Edwin W. Hale of New York, in discussing Mr. Ingalls' paper, stated that according to his electric zinc smelting experience a safe estimate for power consumption is 1,600 kw.-hr. on a 35 per cent zinc ore. In addition to the zinc, he recovered the lead as base bullion and copper as matte. The big advantage of electrothermic smelting is the automatic saving of the by-products. Prof. Richards stated that the furnaces in operation at Trollhattan were not strictly resistance furnaces, but modified arc furnaces. Another interesting process he had witnessed abroad was the recent invention of Cornelius for conglomerating blue powder by rubbing. C. S. Witherell of New York pointed out that the success of any zinc process was dependent upon the quality of the product. A lead-free zinc is in great demand, in particular for alloy work, and there is very little of this product on the market today. The blue powder Dr. Richards referred to contains 20 per cent lead, and accordingly after conglomeration it is necessary to redistill.

STUDIES ON THE ZINC CYANIDE PLATING SOLUTION

In a recent issue of *CHEMICAL & METALLURGICAL ENGINEERING* (vol. 25, page 607) it was estimated that the potential aggregate production of electrolytic zinc for the world amounts to about 250,000,000 lb. per year. The electrolyte is zinc sulphate. Reviving the interest in the cyanide electrolyte, Dr. Chris. J. Wernlund of the Roessler & Hasslacher Research Laboratories, Perth Amboy, reported at length upon "Deposition of Zinc From the Zinc Cyanide Solution." It would seem that although the sulphate electrolyte has much in its favor for the winning of zinc from its ores, in plating practice the cyanide bath is to be preferred. Mr. Wernlund has evolved a zinc cyanide plating solution which will operate successfully under the most trying commercial conditions—i.e., at very high current densities in mechanical plating units where the cleaning of the work is often poor. Following is the composition of the bath recommended, the weights being expressed in ounces per gallon: zinc cyanide 8, sodium cyanide 7, NaOH 1 to 2, Na_2CO_3 4, NaF 1, corn sirup 1, gum arabic $\frac{1}{2}$; temperature of solution 40 to 50 deg. C.; voltage 3 to 5. Very smooth, grayish-white deposits were obtained. The electrolyte does not deteriorate on standing idle.

Dr. Blum took exception to Mr. Wernlund's sweeping conclusions, since the tests at the Bureau of Standards (Bureau of Standards Paper 195) indicated that high concentration NaOH zinc cyanide baths were preferable. Charles H. Proctor referred to the ever-increasing rigidity of the automobile specifications on plated parts. Mr. Wernlund replied that he had tried Horsehead anodes and obtained a porous anode coating of copper and lead. Prof. Richards suggested using as anodes the new zinc cathodes as produced at Great Falls and at Park City without first melting into special shapes, thus avoiding introduction of impurities during melting. Both Richards and Blum lamented the loose way in which the term "throwing power" is used by platers. There are many factors to be considered, such as ion (and not merely "metal") concentration, specific conductivity, and spacing of electrodes, as Witherell added, before fair comparisons are at all possible. George B. Hogaboom, in his usual enthusiastic style, discussed the

increasing importance of closely controlling the compositions of the electrolyte by analytical and physico-chemical means.

ELECTRODEPOSITION OF LEAD-TIN ALLOYS

W. Blum and H. E. Haring of the Bureau of Standards presented a paper on "The Electrodeposition of Lead-Tin Alloys." In the effort to find a satisfactory metallic coating for the inside of air-flasks of naval torpedoes, James S. Groff, chief chemist of the Naval Torpedo Station at Newport, R. I., discovered that it is possible to deposit electrolytically from either fluoborate or fluosilicate solutions an alloy of about 50 per cent lead and 50 per cent tin which has the desired properties. This process, which has been patented by Mr. Groff¹ is now used successfully for the above purpose by the Navy Department. At the request of that department, the Bureau of Standards conducted an investigation to determine the most favorable conditions of operation, and the authors found that it is possible to deposit from fluoroborate solutions alloys of lead and tin, which are finer grained than either of the metals deposited under similar conditions. Lead and tin can each displace the other from such solutions, until an equilibrium is reached, at which the two metals have the same potential. During continued electrolysis with lead-tin anodes, of solutions containing lead and tin, the ratio of the metals in the deposit always tends to approach that in the equilibrium solution.

Charles H. Proctor mentioned that automobile manufacturers would certainly welcome any improvement in applying solder to small steel parts that would lose their temper if heated by the ordinary soldering operations.

William Blum's paper on "The Structure and Properties of Alternately Electrodeposited Metals" will be published in a subsequent issue of *CHEMICAL & METALLURGICAL ENGINEERING*.

Report on the Activities of the Research Council

At the conclusion of the symposium, Paul Moore reported briefly on the activities of the Research Council. The Council was endeavoring to raise enough capital to permit investigators such as Dr. Blum to go on with their investigations unhampered. It is proposed to solicit a subscription of \$100 from each of the large plating concerns. As regards the subject of corrosion a steering committee has been selected, of which William M. Corse is chairman and Dr. Colin G. Fink secretary. The Alloys Information Service and the Committee on Tables of Constants are making good progress.

Meeting of the Board of Directors

The directors of the society met at dinner Thursday evening and again at luncheon Saturday noon.

The invitation of the Baltimore chemists and engineers was definitely accepted. Accordingly, the spring meeting of the society will be held at Baltimore. William H. Boynton of 509 Rose Hill Terrace, Baltimore, is chairman of the committee on arrangements. At this coming meeting there will be a symposium on Electromotive Chemistry in charge of Dr. William C. Moore of the U. S. Industrial Alcohol Co.

The board voted to increase the price of the bound volumes to \$4 to meet the increased cost of publication. It was furthermore decided to publish a ten-year index covering volumes 21 to 40 inclusive.

The Division on Electrodeposition was formally in-

¹U. S. Pat. 1,364,051, Dec. 23, 1920.

augurated. This division covers the fields of electrolytic refining, electroplating, electrogalvanizing, etc., with Dr. William Blum of Washington as chairman.

The resignation of Dr. P. G. Salom, for many years treasurer of the society, was accepted and Messrs. Hering, Salom and Richards were appointed a committee to report on the finances of the society. A nominating committee comprising Messrs. Fink (chairman), Hering, Mott, Lidbury and Gibson was instructed to report back to the board before Dec. 1. The committee is not an "electing" committee, as is the case in some societies; it will suggest several names for each office of the society to be filled during the term 1921-1922.

Social Features

The outstanding social event that will be remembered for many days to come was the "swimming race" up Mount MacIntyre, in which the ladies in particular distinguished themselves.

An exceptional treat was offered the members on Thursday evening when Prof. Harlow Shapley of the Harvard University Observatory gave a very fascinating illustrated lecture on "Chemistry and the Stars." Remarkable views of the heavens were shown taken through the Mount Wilson telescope, the largest in the world. It was amusing to hear mere electrochemists discussing nebulosity, nebium and light-years.

The subject of Friday evening's lecture was "Practice of Forestry on National Parks," a very timely and fitting topic. Colonel T. S. Woolsey, Jr., told of the practice in both Europe and America. The timber supply of this country, he said, will last but twenty years more at the present rate of consumption. It takes from 100 to 150 years to grow saw timber; pulpwood requires 40 to 50 years. In discussing the pulpwood growth, Dr. William H. Gesell of Bloomfield referred to the use of catalysts in hastening the growth of trees. Experiments are being conducted by the Brown Co.

Dr. Melvil Dewey, president of the Lake Placid Club, extended a hearty welcome to the society and outlined briefly the history and purposes of the Lake Placid Club.

A cordial reception and tea was tendered the members and their guests at Dr. Dewey's home, situated in the most beautiful spot in the Adirondacks. Here Dr. Dewey demonstrated the secrets of successful filing and his well-known decimal system.

The one pastime which found favor in the eyes of the greatest number of members was golf. Some enthusiasts played nine holes even before breakfast. On Saturday evening Dr. J. V. N. Dorr, chairman of the golf committee, distributed the prizes. L. J. Buck received a fine club for the best score in the kickers' handicap. John B. Glaze got a second prize, a Monel metal golf head. Dr. Parmelee, editor of CHEM. & MET., and Mr. Terry of the Dorr Co. were rewarded for the most sensational plays in the foursome. Mr. Corse drew four golf balls, and Mr. Baily a tee for modesty in the kickers' handicap, having asked for a handicap of 68. To Mrs. Baily was awarded the ladies' prize, a ball which will automatically retrieve. At 10 o'clock Saturday evening the club arranged for a magnificent fire and water spectacle on Mirror Lake.

Sunday morning, amid animated farewells, the many who had come in automobiles departed, and as they passed and repassed each other on the downward trail, goodbyes and parting sallies flew from car to car. Thus ended what will be remembered by all as one of the most delightful episodes in their lives.

Water-Power Resources of Canada

During the past two years there has been under way in the Dominion Water Power Branch of the Canadian Department of the Interior a careful re-analysis and computation of Canada's water-power resources. All existing stream flow and power data available from dominion and provincial sources have been systematically collated, analyzed and co-ordinated with a view to preparing, on a uniform basis from coast to coast, revised estimates of the power available. While the analysis is not yet finally completed, sufficient progress has been made to warrant the publication of the figures given herein.

The figures listed in the accompanying table are based upon rapids, falls and power sites of which the actual existent drop or the head possible of concentration is definitely known or at least well established. The power estimates have been calculated on the basis of 24-hour power of 80 per cent efficiency for "ordinary minimum flow" and "estimated flow for maximum development."

An analysis of the water-power plants scattered from coast to coast concerning which complete information is available as to turbine installation and satisfactory information as to stream flow gives an average machine installation 30 per cent greater than the six-month flow maximum power. Applying this, the figures quoted therefore indicate that the at present recorded water-

AVAILABLE AND DEVELOPED WATER POWER IN CANADA

Province	—Available 24-Hr. Power at 80% Efficiency—		Turbine Installation, Hp.
	At Ordinary Min. Flow, Hp.	At Est. Flow for Max. Dev. (Dependable for 6 Mos.), Hp.	
British Columbia	1,931,142	5,103,460	304,535
Alberta	475,281	1,137,505	32,492
Saskatchewan	513,481	1,087,756	
Manitoba	3,270,491	5,769,444	83,447
Ontario	4,950,300	6,808,190	1,052,048
Quebec	6,915,244	11,640,052	925,972
New Brunswick	50,406	120,867	21,180
Nova Scotia	20,751	128,264	35,774
Prince Edward Island	3,000	5,270	1,933
Yukon and Northwest Territories	125,220	275,250	13,199
	18,255,316	32,075,998	2,470,580

power resources of the dominion will permit of a turbine installation of 41,700,000 hp. In other words, the present turbine installation represents only 5.9 per cent of the present recorded water-power resources.

The total hydro-power development installed during the past year or now under construction represents approximately 560,000 hp. of installed capacity. This figure includes only the initial installations of plants under construction, not their ultimate designed capacity.

Should the rate of water wheel installation during the past fifteen years be maintained, there will be installed in 1925, 3,360,000 hp.; in 1930, 4,110,000; in 1935, 4,860,000, and in 1940, 5,600,000. There is every reason to expect that the rate of growth in utilization will be accelerated rather than retarded.

The water power now developed in Canada represents an investment of \$475,000,000. In 1940, should the rate of growth in installation during the past fifteen years be continued, this investment will have grown to over \$1,000,000,000. The present development represents an annual equivalent of 18,500,000 tons of coal, which, valued at \$8 per ton, represents \$148,000,000. In the year 1940 these annual figures will, with the foregoing assumption, have become 42,000,000 tons and \$336,000,000.

Industrial Training and Selection of Personnel

An Analysis of Some of the Common Shortcomings of Industry and School—Outline of the Basic Principles Underlying Modern Methods of Selecting and Training Employees, and Some Helpful Suggestions for Solving Personnel Problems

BY C. R. DOOLEY

Manager, Personnel and Training, Standard Oil Co. (New Jersey)

“**S**QUARE pegs in round holes” is an old figure, though none the less true; yet it contains an implied suggestion that round pegs in round holes, all working smoothly, would be an ideal condition. Not so—that is, if the fitting of the pegs and holes is to be done by some automatic system, even a scientific one. In the end people will not be content with being put in their right places; the process must be self-determinative. Otherwise life is not worth living, and as long as dictated authority rules there will be unrest and terrible waste. No one will or can do his best unless he is following his own ambitions, developing his own life. How then can individual freedom be co-ordinated into a single effective effort for the good of the whole community? This is the whole problem of industrial organization, toward which I hope to be able to contribute a few helpful suggestions—not a solution—in connection with the selection and training of men and women within industry.

WISE POLICIES OF RECOGNITION AND PROMOTION

First, the progress of any individual within an industry must be according to merit, and merit alone. Recognition and promotion must have nothing to do with family relationships, society or club memberships, personal whims of high officers or even the ownership of the business. There must be no more chance of a position of foremanship being given to a man because of his connection with the general manager than the captaincy of an athletic team should go to the owner of the athletic field.

Recently an officer of a large corporation needed a secretary and proposed the daughter of an old friend, to whom he was indebted for many favors. However, the personnel manager was able to persuade him to advance one of the young women within the company, thus preserving the morale among a hundred young women, each of whom hopes for advancement and works diligently to deserve it.

The chance for recognition may be one in a thousand, but upon that spark of hope hangs the highest grade of efficiency. Nothing is so deadening as the hopelessness of recognition in the face of inherited or political advantages. Merit is of course not always easy to determine, even when an honest effort is made. In the last analysis one man's merit is largely another man's judgment. But men do not resent the frank honest judgment of their superiors so long as they know they've had a fair chance. Every day one hears criticism of favoritism, but over a long experience I have never heard an honest judgment criticized even if very disappointing.

Perhaps the second most deadening influence to initiative and creative effort is a blanket seniority rule. A good rule, other things being equal—but other things

never are equal. In matters of discharge as well as promotion the personal record and personal qualities alone should count. Such a policy is a far greater stimulus to young men than increased wages.

Assuming now that our policy is “Let the best man win,” how is he to be selected with reference to the work he is to do, and then how is he to be introduced to his work? These are big questions, and again I can only make a suggestion or two.

ADAPTABILITY OF THE INDIVIDUAL

It is a fallacy that all men are created equal. Each of us can do certain things better than other things, therefore we should not expect all young men to climb the same ladder to success. A promising young salesman may be poor at routine office work, yet he may need a certain amount of experience in the office before he is given a larger sales position. Indeed a good sales manager may not be an especially successful salesman. A chemist producing many improvements in processes each year may not be the man to place as manager of the research department.

It is difficult to transfer a man successfully from one general branch (such as manufacturing, accounting and selling) of a business to another branch, not only because his previous experience has been so decidedly different, but because of certain fundamental native qualities of mind and personality. Most men, if started right, will advance most successfully by remaining within a given branch of a business. Then again men differ as to their adaptability to outside or inside work, and also as to their ability to start new enterprises or to close and finish them. Some men are by nature individualists; they work best absolutely alone; system and assistance hamper them. These must not be discharged for lack of discipline, but used where their kind is needed. Others need the close association of other men's minds in order to contribute their best. These are organization men, better for planning than executing. So all men should be considered as to their type—manufacturing, accounting, commercial, financial, promoting, scientific, office, field, organization, etc.

Men of middle life are obviously selected because of their attainments, personal or technical. They will largely take care of themselves, but young men should be selected for their potentialities, their native qualities and possibilities of development.

BASIS FOR SELECTING YOUNGER MEN

Confining our attention from now on to the problem of the young man, the basis of his selection should be a series of rather personal questions in an effort to find out a great many things the man has done since he was a small boy and what his motives have been.

As a child did he wear out the toys his parents bought him, or did he invent and make his own playthings? If he sold papers, what methods did he devise to carry on the business and did he operate his own business or carry papers for another man? If he worked his way through school, just how did he do it? How much money has he earned during vacations? At what kind of work? What did he do with his money? If he has had several jobs since leaving high school, what were they and why did he change? Is his purpose always placed ahead of the pleasure of the moment? To have done his duty is expected, but how clearly has he had some kind of plan even in boyhood?

If he carried responsibilities as a boy, he will be apt to carry them well as a man. If he had a commercial interest as a boy, he probably will continue in that as a man; and if he was clever with simple mechanical devices as a boy, he will continue to exercise a constructive imagination with mechanical things as a man. A few fundamental types of men seem to hold true clear back to their earliest recollections. Some of these types are: inventive or constructive engineering, analytical or research engineering, commercial individualist, and commercial organizer.

The interview, of course, should include all such personal data as age, parentage, place of birth, business of parents, habits, athletic interests, height, weight, color, etc. Some rules may hold true generally but there are many exceptions, and only when you know the whole story of a man can you make a final estimate.

IMPORTANT QUALIFICATIONS TO BE CONSIDERED

There are many desirable personal characteristics, and each interviewer will emphasize different ones. There can be no one standard list of qualifications for all interviewers to use, but anyone attempting to select young men should adopt some list of qualifications which he believes more or less describe a man. I have found that different men pick equally good men, although each uses different methods and each calls the important qualification by different names. In general, the following characteristics may be considered in selecting young men for training in any business:

1. *Moral Fiber*.—Integrity, honesty, reliability, a spirit of helpfulness, modesty, refinement, ability to work in an organization, co-operativeness, tactfulness, etc. In short, those things which make a man liked and respected and trusted among his fellow-men. He is acceptable.

2. *Personal Power*.—Originality, initiative, resourcefulness, vision, ability to discriminate between essentials and non-essentials; courage, readiness to accept responsibility, understanding of men, etc. In short, those things which designate a man as an original contributor in some way to the world's progress. He gets things done.

3. *Technique*.—Technical knowledge, special experience, kinks of a trade or profession, data, formulas, etc. In short, those facts which he acquires either from books or from experience. He knows how.

To summarize these points in the reverse order, the third represents the required tools with which he works; the second is his ability to use these tools; and the first is his character, or his passport which permits him to work with the rest of us.

The majority of young men, especially those graduating from college, have the first of these qualifications

and a considerable portion of the third; but, on the other hand, two-thirds of them are lacking in the second.

THE BASIC PRINCIPLE IN EFFECTIVE TRAINING

With this general philosophy as a background, it is necessary to develop a method of training which will not only teach men a certain number of technical formulas but will develop within them the originality and initiative necessary to successful original application of these formulas. After a number of years of experimenting with young men varying in age from fourteen to thirty, some having only a part of the public school education and some having been graduated from college, there is one universal deduction which may be stated here as the basic principle in all effective education or training, whether in the academic class room or the practical shop.

Technical information should be presented to students in the form of jobs or problems or projects or questions, and these should be presented in advance of formal explanation of methods of solution.

Many problems simply take the form of questions, but the answer to these questions should never be given in systematic form. Of course, the problems and questions must be arranged in some order of difficulty, so that each problem means a step forward. Obviously a young machinist should not be started on a gear-cutting machine before he has had some of the simple bench and lathe work, or a young salesman should not be sent to the most difficult customer first. On the other hand, each job that is put up to either of these two men should be a real job and not have all of the punch taken out of it by being thoroughly explained beforehand. Memorized lectures do not stick with us; or if they do, they never become a part of our real experience. They are always superficial in their relation to our best actions.

MUCH TIME AND PATIENCE REQUIRED

It is a difficult and serious task to teach by this method. It takes time and much patience. For the head of a department to explain carefully to his young assistant all of the difficulties which the young assistant is likely to encounter during the day, or to explain nothing, but merely storm at him at the end of the day after he has made a mistake, are both easy things to do.

The old "sink or swim" methods produce poor swimmers and many drownings. On the other hand, too many swimming lessons given on land take all of the spirit and initiative out of men by teaching them in detail how swimming is done but never how to swim.

The right thing to do and the difficult thing to do is to give just enough fundamental information at the beginning to set the boundaries or policies within which the young man is expected to act, and then at a later time to discuss with him the details of his experience in a way which will help him to analyze them and come to his own correct conclusions.

Many department heads object to instructing new men continuously and losing them even to other departments within the same organization. They prefer low-grade men who "stay put" to men of larger ability and ambition. There may be a question as to the number of high-grade men to train in any one organization, but there can be no doubt as to the most effective method of training, and further this method will show that all men are better than had been supposed—and that some are a great deal better.

When this process becomes too burdensome to the executive staff, it is time to set up a special training school. The method is simple: First you provide a series of actual work assignments where the experience is real, and then you provide a series of class meetings for discussion of each man's experience, following an outline of problems and questions which are given him in advance.

The instructor now becomes a mere referee who decides disputes and sees to it that the men do not get wrong information. He insists that the answers to all questions be deduced from the personal experience of each man, and by continual quizzing he keeps the men going in the right direction. A lecturer is the poorest kind of a teacher for developing real personal power. Occasionally a lecture or talk given by some officer or expert has a good effect by way of general inspiration, but this part of an educational program should be a small percentage.

SELECTING THE PROPER SORT OF TEACHER

The best kind of teachers are men selected right from the offices or shops, each man an authority in his subject. All men who are competent workers do not make good teachers, but all teachers should be competent in their work or profession and should be engaged in the practice of it, giving only a portion of their time to teaching.

In addition to being competent at his work, a teacher should have an inspiring personality and an enthusiastic way about him to get under the skin of young men. Generally a man who is competent at work and who expresses a keen desire to teach purely for the love of helping young men makes a good teacher. Such a man should be young enough to be flexible so that the head of the training department can mold him in the understanding and practice of this general philosophy of teaching. He must be interesting and his class meetings must be interesting.

METHODS OF INSTRUCTION WHICH DEVELOP INITIATIVE

This is the whole trouble with teaching. We teach young people how things have been done instead of why they are done or, better yet, we should teach them to think out for themselves the "why." Instead we standardize forms to be memorized and call it education. We not only standardize arithmetic, but we standardize the method in which it shall be presented, adopting a full set of technical terms. For example, when the young student finishes simple interest in the public schools he turns over a page and begins compound interest, which he has heard from his fellow students a grade ahead of him is exceedingly difficult, and accordingly he enters upon its study with diffidence.

Now the fact is that, mathematically speaking, there is no such thing as compound interest. It is only simple interest repeated with a new principal. The new principal is the old principal plus the interest for a given period which a man has been unable to pay when due. The reason that it is due on a given date and that after that it becomes a part of the new principal is purely a matter of custom among people, and has nothing to do with mathematical principles. If this were explained in connection with problems in simple interest and then the name "compound interest" given merely incidentally as a convenient term to use in talking about such a

problem, the whole subject of compound interest would disappear.

The same thing is true of electricity, which I have studied thoroughly, practiced intensively and taught personally to almost every kind of student. Some of the electrical theory is complex and difficult, but a great deal of it is exceedingly simple when stripped of its mysterious terms.

The average shop mechanic pays profound respect to a piece of blue paper covered with white lines, and yet blueprinting has nothing to do with mechanical drawing, but is only a means of cheap duplication. Even the principles of drawing are mystified by a technique called "projection." Mechanical drawing is a language used to express ideas in terms of flat surface pictures and is not a matter of beautiful lettering and shading of lines. The fundamentals are as simple as arithmetic and could easily be taught in the grammar grades without either blue paper or expensive drawing tools.

We continually shroud ourselves in technical terms which we endeavor to force young people to memorize, and in so doing we tend to crush what originality and initiative they have in the beginning. In teaching technical subjects only fundamental principles should be considered and great emphasis should be placed upon their correct application to original problems, free from tradition and customs. Of course, as society is organized, a certain amount of form is called good. We must have correct spelling and some style to our dress, and yet the moment form begins to add to our dignity rather than to our efficiency we begin to stifle initiative and originality.

BRINGING THE INDUSTRY AND THE SCHOOL TOGETHER

All of this is a very roundabout way of saying that in our training processes we must first of all develop what we may call industrial intelligence and not merely require routine memorized formulas and standardized methods. We must encourage men to vary from things as they are today. We must stimulate the research point of view, the habit of eternal inquiry after better ways, for only through this can we ever hope to develop the leaders of the future.

This can be done normally and without forcing by beginning with the work, or the job, and approaching the student with a discussion of many questions about the job. If the student rises to the occasion and comes back with original contributions, you know he is growing and it is your business, employer as well as teacher, to keep him growing to the limit of his capacity. Some men will never respond greatly, and therefore will continue in the routine performance of their present work. All of us cease to respond sooner or later and thereby we find our level.

The trouble with our schools has been that they artificially pull people above their levels by forcing memorized formulas.

The trouble with industry has been that it artificially holds men below their levels through lack of opportunity to study out the science underlying their work, and through arbitrary authority.

When these two things are brought together—when the spirit of the teacher pervades industry and the spirit of production furnishes the background for education, then all people will find their levels automatically and remain there without chafing under arbitrary authority.

To make this function in practically any organization, two kinds of training must be provided: (1) That which young men just starting into business are obliged to take because of a company's determination to select and train for efficiency. (2) That which any man in the business who is ambitious to improve himself may take according to his own option.

THE THREEFOLD PURPOSE OF TRAINING

In both cases, however, the method of teaching should be the same and should have a threefold purpose: (1) To inspire the highest quality of American manhood, although if a man has not a fine moral fiber, integrity, honesty, reliability, etc., he is not worth the trouble of training. (2) To discover and develop personal power in the use of knowledge under new and trying circumstances. (3) To establish a certain amount of accurate fundamental knowledge.

No matter how large and complex the organization, each individual must be treated upon his own record, as an individual in open frank honest competition with his fellows. Training courses, for the most part optional, must be available to guide young men and women in working out their ambitions and to assist department heads and officers of concerns in the discovery of latent talent. The routine work of the day serves well to develop character, to test out loyalty, obedience, thrift, etc., but it is often not stimulating and intellectual depths are not challenged. On the contrary, practical problems presented by an inspiring instructor in the class room appeal to the intellectual powers and bring out latent abilities not hitherto suspected. Moreover a training program fills young employees with the belief that they have a chance, that the "Old Man" is now going to play square with them. With this attitude of mutual confidence and mutual helpfulness the pegs will find their proper holes naturally.

Personnel adjustments to be successful must be done impersonally by the authority that comes from skill and special knowledge and not the authority of official position.

There are managing talents and special abilities among the rank and file of people, if those in authority will only take the trouble to find them—and be willing to give them a chance according to their true merit.

New York City.

Canadian Linseed Oil Industry in 1918

Though no statistics from which comparisons can be drawn have been compiled previously to those just issued by the Canadian Bureau of Statistics for 1918, the production of flax seed and the manufacture of linseed oil in Canada are industries that are beginning to assume considerable proportions. During 1918 more than 6,000,000 bu. of flax seed was produced, about half of which, having a value close to \$8,000,000, was exported. Of the remainder 1,360,000 bu. was used for the manufacture of oil, and from this was produced 1,144,000 gal. of crude and 738,000 gal. of refined linseed oil, having a combined value of \$4,063,000, and 24,366 tons of oil cake, having a value of \$1,374,500.

Seven plants, representing an investment of \$2,500,000 for land, buildings and machinery, were in operation during the year and nearly \$200,000 was distributed in wages. Sundry byproducts, such as greases, stearine and fertilizers, also were manufactured at the several plants.

Hardness Variations in Heat-Treated Steel

BY CARLE R. HAYWARD

IN STUDYING the properties of different steels the writer has often been struck by the fact that the center of a heat-treated bar is with rare exceptions harder than the material nearer the edge. This difference in hardness has been most noticeable when testing with the Shore scleroscope, for a majority of the specimens have been only $\frac{3}{4}$ in. in diameter and the Brinell tests were taken only at the center.

I have made no extensive series of tests to study adequately the progressive change in hardness from center to circumference, but a few figures giving values obtained with several steels may be of interest and may possibly call forth others from other investigators.

One steel with an analysis C 0.42, Si 0.07, Mn 0.79, S 0.015, P 0.016 after quenching in water from 850 deg. C. and reheating to 400 deg. gave the following hardness tests on a polished cross-section:

Time Reheated	Shore Test at Center	Shore Test Near Edge
15 min.	30	28
30 min.	29	25
1 hr.	27	20
4 hr.	26	19

In another series of tests the steel used had the following analysis: C 0.46, Mn 0.56, S 0.055, P 0.010.

The specimens $\frac{3}{4}$ in. in diameter were quenched from 850 deg. in tap water and reheated to 300 deg. for 5 min., 15 min., $\frac{1}{2}$ hr., 1 hr., 2 hr. and 4 hr. Another piece in the original condition was annealed at 850 deg. for 15 min. and cooled in the furnace. The scleroscope tests on a polished cross-section were as follows:

Time Reheated	Shore Test Center	Av. of Six Tests Nearer Edge
Quenched	45	42
5 min.	30	24
15 min.	32	27
30 min.	25	20
1 hr.	25	17
2 hr.	29	25
4 hr.	32	28
Annealed	17	15

Although these results seem somewhat inconsistent, one striking point is brought out. In 5 min. reheating, the hardness dropped to two-thirds the figure found for the quenched specimen and remained approximately constant for 4 hr. In every case the center was harder than the average of the remaining surface.

Another steel of nearly the same composition was quenched in the same way as above, but the reheating was carried out at 400 deg. C. Composition of steel: C 0.44, Mn 0.58, S 0.042, P 0.007.

Time Reheated	Shore Test Center	Av. of Six Tests Nearer Edge
Quenched	47	43
5 min.	36	33
15 min.	32	22
30 min.	27	23
1 hr.	23	17
2 hr.	27	19
4 hr.	25	21
Annealed	18	16

With the exception of the 1 hr. treatment the figures are in this case consistent. The drop in hardness during the first 5 min. heating is again striking, though in this case it is only 20 per cent instead of 33, as in the 300 deg. heating.

A third $\frac{3}{4}$ -in. steel bar varying slightly from the last two was quenched in the same way, but reheated to 500 deg. C. Composition of steel: C 0.48, Mn 0.58, S 0.048, P 0.007.

Time Reheated	Shore Test Center	Av. of Six Tests Nearer Edge
Quenched	44	45
5 min.	30	26
15 min.	25	18
30 min.	26	21
1 hr.	20	17
2 hr.	26	22
4 hr.	28	23
Annealed	20	17

The tests on these specimens were somewhat erratic, but again the same tendency is brought out.

All the above figures were obtained incidental to other tests. In order to see what effect heating to 700 deg. would have on the hardness three pieces of the last steel were quenched and heated for 20 min., 1 hr. 10 min., and 2 hr. respectively at 700 deg. C. The results were as follows:

Time	Shore Test at Center	Shore Test Half Way to Edge	Shore Test Near Edge
20 min.	24	20	17
1 hr. 10 min.	23	20	15
2 hr.	23	19	15

These results are nearly the same as on the annealed specimens. It is interesting to note that practically the full effect took place in the first 20 minutes.

Some pieces of $\frac{3}{4}$ -in. round carbon tool steel containing 90-100 point carbon were quenched in water from 850 deg. C. and reheated for 20 min., 1 hr. 10 min. and 2 hr. at 350 and 600 deg. C. The hardness results were as follows:

Time of Reheating	Shore Test at Center		Shore Test Half Way to Edge		Shore Test Near Edge	
	350°	600°	350°	600°	350°	600°
20 min.	29	26	27	25	25	23
1 hr. 10 min.	30	25	28	24	28	22
2 hr.	30	24	28	22	27	20

Again there is a difference between the center and the edge, but not so great as in medium-carbon steel.

All the figures thus far presented are with the Shore instrument. In order to get some results with the Brinell machine some pieces of 2-in. steel shafting 2 in. long were quenched in water from 850 deg. C. and reheated to 350 and 600 deg. for 20 min., 1 hr. 10 min. and 2 hr. They were then sawed at the middle, polished in cross-section and tested.

Time	Shore Test at Center		Shore Test Half Way to Edge		Shore Test Near Edge	
	250°	600°	350°	600°	350°	600°
20 min.	24	22	23	21	22	20
1 hr. 10 min.	24	22	23	21	22	20
2 hr.	23	23	22	21	22	21

The Brinell hardness of the last specimen was center 149, half way to edge 137, near edge 126.

This steel is so low in carbon that the Shore test shows little variation either for temperature or time. The Brinell numbers are more divergent than the Shore numbers.

DISCUSSION OF RESULTS

The figures, taken at random as they are from the writer's files and obtained from a variety of steels, are in no sense an adequate research into hardness phenomena from which definite conclusions may be drawn.

There are several indications regarding the effect of temperature and time on hardness which more data might confirm or disprove, but one fact is outstanding: All cases cited and many more which are not mentioned in this paper show a greater hardness at the center than near the edge, regardless of heat-treatment. This is not due to decarburization, for the tests were made far enough from the edge to avoid this.

The probable explanation is either the McCance inter-strain theory or possibly the theory recently published by Jeffries and Archer.

All steel on cooling is subjected to internal strains varying in intensity with the rate of cooling. Even a steel very slowly cooled is subject to a small amount of this strain. It is evident that in all cases the effect is greatest at the center of the specimens and according to the new theory a variation in hardness is to be expected. Once hardening by slip or interference in grain growth is produced, varying from center to outside, it is impossible to eradicate it completely. At drawing temperatures near the critical range equalization is approached, but if it is ever attained during heating, which may fairly be doubted, a slight differentiation takes place during cooling. E. E. Thum has suggested to the writer that at least part of the excess hardness at the center, especially that shown after complete annealing of the specimens, may be due to the segregation which always occurs to some extent at the center of an ingot and persists in rolled bars. This fact should not be overlooked, for it is a reasonable explanation of at least part of the phenomena. The entire explanation can be found only by a careful research involving chemical analyses from center to circumference supplementing the hardness data and microscopic analysis. It seems fair to assume that it is practically impossible under ordinary heat-treatment conditions to expect a bar of steel to be homogeneous in hardness throughout its cross-section.

Wood Acids*

"Acid" is a term used by many to designate almost any kind of chemical which has a corrosive action, and, in the same loose sense, the term "wood acid" is used in explanation of any unusual quality in a wood, such as taste, odor or corrosion of metals in contact with the wood. As a matter of fact, only three chemicals correctly called acids have been found existing free in wood; these are tannic acid, acetic acid and formic acid. Tannic acid is very feeble and has very little corrosive action on metals. The two other acids are also feeble in comparison with sulphuric, nitric or hydrochloric acid.

A very small amount of acetic acid and a still smaller amount of formic acid apparently exist in all native woods, probably as the result of a slow action of water on wood at ordinary temperatures. All native species are also alike in that both of these acids can be produced very readily from them by the simple action of steam or hot water, a reaction for which there is no simple preventive treatment. Acids formed in the wood by the agency of steam or hot water are doubtless responsible for the results frequently attributed to acid supposed to have been in the wood originally.

The amount of acid normally present in any native wood is not sufficient to warrant its rejection for any purpose involving contact with metals.

The Amorphous Metal Hypothesis

The Amorphous Metal Cement Hypothesis Is the Only Satisfactory Explanation of the Properties of the Grain Boundaries in Metals—The Role of Amorphous Metal in Plastic Deformation and Particularly in Producing Hardness Has Been Greatly Exaggerated

By ZAY JEFFRIES AND R. S. ARCHER

ALTHOUGH solid metals are in the main undoubtedly crystalline in structure, there is reason for supposing that they may exist partly in an amorphous condition, and that those portions which are amorphous may exert a very important influence on the properties of the aggregates. This view was first advanced some twenty years ago by George T. Beilby¹ largely as a result of his studies on the nature of polished surfaces. It has since been elaborated and extended, notably by Rosenhain², so that the amorphous metal hypothesis now occupies an important but somewhat uncertain position in modern metallographic theory. It is the purpose of this article to recount the principal elements of this hypothesis and to present a critical discussion and a statement of the hypothesis which is believed to be consistent with the results of recent research.

DEFINITION OF "AMORPHOUS"

Crystalline materials are characterized by the orderly arrangement of their constituent particles—i.e., atoms or molecules—in definite geometrical patterns. Materials whose molecules do not possess any such regularity of arrangement are amorphous. The term "amorphous" is thus in the broadest sense directly opposed to crystalline. A further distinction must be made. Wood is a material which is decidedly not crystalline, and yet because of the processes of its growth it possesses definite directional properties. The arrangement of its atoms or molecules is not entirely haphazard. The same is true of all vegetable and animal tissues. In order to define more specifically what he meant by the term amorphous in connection with metals, Beilby used the qualifying adjective "vitreous," narrowing the field to "substances which in some degree resemble the glass-like form assumed by the silicates when they are solidified from the molten state."

Amorphous solids are essentially undercooled liquids of great viscosity. The constitution of the liquid is preserved and with it the property of fluidity, masked from casual observation by the high viscosity. Glass may be taken as an example. On cooling from the molten state it passes in a continuous manner from a liquid which can readily be poured to the solid we know at ordinary temperatures with a hardness comparable to that of the hardest steel. In spite of this hardness, a rod of glass supported at the ends will sag or "flow" under its own weight in the course of months or years.

It has been pointed out in a previous article³ that the regularity of atomic arrangement in crystals leads to mechanical weakness along certain crystallographic planes. The absence of such planes of weakness in amorphous materials leads to great hardness at low temperatures. The hardness and strength of amor-

phous materials will be discussed later more fully. For the present it is merely necessary to say that the amorphous modification in most metals is regarded as being harder and stronger than the crystalline at ordinary temperatures.

AMORPHOUS FILMS ON RUBBED SURFACES

The studies of Beilby referred to above showed that the operation of polishing causes a surface flow of the material being polished. The action of abrasive materials is essentially one of cutting. The grinding of a metal surface by an abrasive such as emery consists in the cutting of minute grooves, the emery particles acting as cutting tools. When such a surface is polished or burnished, the surface layers of the metal are caused to flow, bridging or filling up the grooves left by the emery. Working with the mineral calcite (calcium carbonate), which is especially suitable for such observations, Beilby found that the flowed surface possessed certain properties which distinguished it from the unpolished crystal face. It was harder, as tested by the loaded needle, and its hardness was the same in all directions, whereas the hardness of the natural crystal face varied according to the direction in which it was measured.

Perhaps the most significant thing is the way in which the polishing operation gradually smoothes over the scratches, finally obliterating them and leaving a surface with an appearance "absolutely homogeneous and vitreous like a coating of varnish or enamel." Furthermore that this smooth surface is merely a coating is demonstrated by the fact that the scratches are again revealed when the surface layer is dissolved in hydrochloric acid. Beilby concluded that the flowed material is rendered amorphous by the action of polishing. This amorphous film was assumed to be in a condition of great mobility at the instant of formation so that under the influence of surface tension it would assume a very smooth surface. It was then supposed to solidify or "set" in the final hard glassy state.

It had already been shown that the permanent deformation of metals takes place by a kind of block movement on certain crystallographic planes known as gliding planes or slip planes. Beilby postulated that the rubbing of the crystal fragments over each other on the slip planes generates films of amorphous metal comparable to the surface films produced by polishing. Like the surface films, they were supposed to pass through a mobile stage and then become hard and rigid. Now the ductile metals are greatly hardened and at the same time made brittle by deformation carried out below the annealing temperature, whether such deformation be effected by cold-drawing, rolling, pressing or other means. According to Beilby's theory, this "hardening" results from the formation at all the internal surfaces

¹See references and footnotes on page 704.

of slip or shear of mobile layers similar to those produced on the outer surface by polishing. These layers retain their mobility for only a very brief period and then solidify in a vitreous amorphous state, thus forming a cementing material at all surfaces of slip or shear throughout the mass." The increased hardness is thus attributed to the presence of a framework or matrix of a modification of the metal possessing greater specific hardness than the crystalline modification.

After this stiffening of the metal, further deformation is forced to take place on new slip planes, thereby producing more amorphous metal and still greater hardness. There is a practical limit to the amount of cold deformation that a metal will endure. Further attempts cause rupture. Thus in wire-drawing if the process is carried too far the wire draws hollow or splinters. Even before this stage is reached maximum hardness and strength are produced. Over-drawing reduces the strength. This is regarded by Beilby as due to the exhaustion of available crystalline material. The crystalline modification of the metal is regarded as the sole source of plasticity and when the available supply is exhausted the metal becomes incapable of further deformation.

RECRYSTALLIZATION

Metals which have been hardened by cold-work are softened by heating to a suitable temperature. The softening is accompanied by the restoration of ductility and by the substitution of a clearly crystalline structure of equi-axed grains for the disordered structure found after cold-working. This operation is called "annealing," and is a regular part of most industrial processes involving the cold deformation of metals. The softening is explained by Beilby's theory as due to the recrystallization of the amorphous metal produced by the cold-work. Disappearance of the amorphous metal of course involves the simultaneous disappearance of the hardness and brittleness supposed to be due to it.

Crystallization of an amorphous solid or undercooled liquid is a common occurrence. Glass and vitreous silica crystallize or "devitrify" when exposed for a long time to temperatures at which they are somewhat soft. The presence of crystalline nuclei greatly facilitates this transformation. Beilby considers the recrystallization of metals to be strictly analogous to that of other amorphous materials in the presence of nuclei. The nuclei are the fragments supplied by the breaking up of the original crystalline grains. The amorphous metal is regarded from the physicochemical viewpoint as identical with the liquid phase. Hence it must be unstable at all temperatures below the melting point of the metal and is prevented from reverting to the stable crystalline form only by its rigidity due to the low temperature. On raising the temperature of a metal the atomic mobility becomes sufficient for the unstable amorphous phase to crystallize about the nuclei already present.

OTHER METHODS OF PRODUCING AMORPHOUS METAL

Beilby did not consider deformation to be the only means for the production of amorphous metal. He recognized that it is not possible to retain metals in the amorphous condition by rapid cooling from the molten state, as is the case with glass, vitreous silica and many other typical amorphous solids. He did, however, advance the suggestion that "the evolution of a dissolved gas when a critical point is reached may so

effectually prevent or modify crystallization that the metal is hardened." And again, "Sometimes a very minute addition of a second substance to a pure metal is sufficient to prevent crystallization in the regular way, or even to prevent it altogether. The product is then more rigid and less plastic than the pure metal." This statement was offered as an explanation of the fact that solid solutions of two metals are usually harder than the pure metals, the case of gold and silver being mentioned as an example. Another suggestion was that amorphization might be brought about by flow occurring in a cooling mass as a result of shrinkage strains. Certain samples of electro-deposited copper are found to be very hard and to possess a structure somewhat resembling that of cold-worked metal. Annealing causes recrystallization and softening. From these observations Beilby concluded that "the deposition of the metal under conditions of strain had caused the molecular aggregation to be of the amorphous type." These suggestions are interesting to note in tracing the development of the theory. Beilby sums up thus:

"The development of the maximum intrinsic hardness of the metals can thus be brought about in many different ways, but in every case it appears to depend on the special development of the cohesive forces which is associated with the amorphous or non-crystalline aggregation of the molecules."

WHAT CEMENTS CRYSTALLINE GRAINS TOGETHER?

In 1912 Beilby's hypothesis received a very important extension, consisting in the proposition that the amorphous phase exists not merely in cold-worked metals but is also a normal constituent of all metals in the form of an intergranular cement.* Beilby's original hypothesis that amorphous metal is formed on slip planes during plastic deformation was put forth to explain hardening. The postulation of an amorphous intergranular cement was advanced to explain an entirely different set of phenomena, which will now be briefly described.

When pure metals that are in what may be called "a normally healthy condition" are broken, the path of fracture is found to pass almost exclusively through the grains, rather than between them. The grain boundaries appear to be stronger than the grains themselves, rather than weaker, as might be expected. When metals are broken at temperatures just under their melting points, however, the conditions are reversed, fracture following the grain boundaries.

Permanent deformation of metals consists of plastic deformation of the crystalline grains, by the process of slip or gliding. If the grains possess any inherent plasticity, as is normally the case in the ductile metals, then fracture through the grains is necessarily preceded by some plastic deformation of the grains and a general deformation of the metal as a whole. Transcrystalline fracture is therefore accompanied by a ductile break. Intergranular fracture at high temperatures, on the contrary, takes place in a brittle manner—i.e., with little if any general deformation of the metal. The cohesion between grains has become so small that they pull apart before sufficient load can be transmitted to deform them.

The assumption that the grains of metals are held together by a cement of a vitreous amorphous nature explains these phenomena in a very satisfactory manner. At the lower temperatures this cement is hard

*See references and footnotes on page 704.

and strong, so that the necessary loads can be transmitted to the grains to deform them and finally cause rupture to pass through them. As the temperature is raised the amorphous cement gradually softens⁵ so that at high temperatures it is very weak. The grains then readily pull apart without any appreciable deformation.

TIME FACTOR IN LOADING AMORPHOUS MATERIAL

Since the atoms (or molecules) of amorphous materials do not occupy fixed positions with respect to one another, such materials can be deformed by the gradual shifting of the relative positions of their particles. The atoms in a crystal of metal are held in substantially fixed positions in the crystal lattice. Deformation therefore takes place by the simultaneous movement of a large number of atoms. A correspondingly large number of atomic cohesion "bonds" must be broken at one time. The result is that the strength (or what is the same thing, its elastic limit in shear) of a crystal is definite. The cohesion bonds in an amorphous material may be broken very gradually—almost one atom at a time, we might say. The force required to produce deformation is therefore very small. Such small forces must of course act for considerable periods of time in order to effect appreciable deformations.

There is a distinct and important time effect in the rupture of metals at high temperatures. At any given temperature which lies well above the annealing temperature of the metal but not too close to the melting point, either intergranular or transcrystalline fracture can be produced at will by varying the rate of applying the load. This is illustrated by some tests carried out on copper wire at a temperature of 950 deg. C.⁶

Time Required to Break	Tensile Strength	Type of Fracture
1 minute	710 lb. per sq.in.	Intergranular, brittle
5 seconds	2500 lb. per sq.in.	Transcrystalline, ductile

It will be noted that not only is the type of fracture changed by increasing the rate of loading but the strength is very greatly increased. This is explained on the assumption of an amorphous intercrystalline cement by the known properties of solid amorphous materials. Attention has already been called to the fact that glass will flow under its own weight acting for a long period of time, whereas it is perfectly elastic up to a stress of perhaps 30,000 lb. per sq.in. under loads acting for short periods. The typical combination of fluidity and hardness possessed by amorphous solids is perhaps illustrated even better in the properties of pitch. At ordinary temperatures pitch can be pulverized by means of hammer blows. If the particles of powder thus produced are put in a receptacle the force of gravity alone is sufficient to weld them into a single coherent mass of pitch. This welding may require considerable time, but it is so effective that even the air bubbles are slowly forced to the surface. Pitch can be deformed into any shape desired if sufficient time is taken. A barrel of pitch, for example, can be emptied by allowing it to flow very slowly from a small hole. At any time during this process of flow, a sharp hammer blow will shatter into fragments the stream of flowing pitch. Pitch is thus either hard and brittle or soft and plastic according to the rate of deformation attempted. Resistance to rapid deformation is very great, but deformation can be effected slowly by extremely slight forces.

Now the crystalline grains of a metal are supposed to be held together by an amorphous metal cement whose

properties at high temperatures resemble those of pitch at ordinary temperatures. At the freezing point of the metal the liquid or amorphous metal has practically no resistance to deformation. At the same time the crystalline metal has very considerable resistance to deformation. The case is similar to that of water and ice at the freezing point of water. As the metal cools, the undercooled liquid or amorphous metal at the grain boundaries increases in viscosity so that at very low temperatures it has great hardness. At the same time the hardness and strength of the crystalline metal increase, but at a less rapid rate. At "high temperatures," which in the case of metals means at temperatures above that of recrystallization, the amorphous metal is softer than the crystalline.

Suppose a piece of metal such as the copper wires mentioned above be subjected to a small tensile load which is insufficient at the temperature of the test to deform the crystalline grains (the force required to deform a crystal is practically independent of any time effect). If this small load is allowed to remain on the test specimen, it will in time cause flow in the viscous amorphous cement and the grains will finally be pulled apart, without having themselves undergone any deformation. The fracture will then be of the intergranular, brittle type.

Suppose a similar specimen to be loaded rapidly to a much higher stress. The amorphous cement will sustain high stresses for short periods of time, so that if the load is applied rapidly enough, a stress can be reached which is high enough to deform the crystalline phase. Fracture will then take place through the grains instead of between them, and will be accompanied by considerable general deformation of the piece as a whole.

HYPOTHESIS OF AMORPHOUS METAL CEMENT

This is in brief the amorphous metal cement hypothesis as proposed by Rosenhain. It was advanced primarily to account for the cohesion between the grains of a metallic aggregate and the changes in cohesion with change in temperature. The development of the hypothesis leads, of course, to conclusions regarding other phenomena, particularly hardness. The amorphous metal at the grain boundaries was supposed to be the same as that proposed by Beilby as the cause of the hardness produced by cold deformation. Any increase in grain boundary surface must therefore result in an increase in hardness. This afforded a ready explanation of the fact that the hardness of metals increases as the grain size becomes smaller. Carrying the idea to the extreme, Rosenhain proposed that the great hardness of hardened steel is due to "the presence of an extremely minute network of amorphous layers" surrounding the very fine grains of alpha iron which result from the rapid transformation of gamma iron. He regarded the amorphous iron as being especially hard in this case because of iron carbide in solution.

Beilby's theory of hardening by the formation of amorphous metal and Rosenhain's conception of an amorphous intercrystalline cement comprise what may be called the fundamental ideas of the amorphous metal hypothesis. These ideas have in some form gained a rather wide acceptance in England and America, although they have not been so favorably received on the Continent. There is at present no unified opinion regarding the details of the hypothesis, which is quite to be expected considering its newness and its speculative nature. It must be recognized that this hypothesis

⁵See references and footnotes on page 704.

concerns some of the most important properties of metals and therefore deserves very careful inquiry and consideration both as to the fundamental ideas and their detailed development.

CAN METAL BE PRODUCED ENTIRELY AMORPHOUS?

The first question to be considered should perhaps be that of the reality of amorphous metal. It is possible by means of the X-ray spectrometer to literally "look into" a metal and recognize the presence of crystalline material. Unfortunately, however, there is no such positive test for the presence of amorphous material. The most direct proof of the reality of amorphous metal would of course be the production of metal *entirely* in the amorphous condition. Beilby attempted to do this by mechanical deformation and he selected wire-drawing as a suitable process because of its drastic nature. After having drawn wires of silver, copper and gold to as much as fourteen times their original lengths, he concluded that they still contained crystalline metal and that it is impossible by mechanical deformation to convert a metal entirely into the amorphous modification. In addition to the microscopic observations upon which his conclusion was largely based, there is an abundance of confirming evidence of a more positive nature.

Beilby considered that he had produced a totally amorphous mass of metal by compressing very fine gold powder precipitated from aqueous solution. He described his product as harder and less plastic than other forms of gold, and also resistant to recrystallization at 350 deg. C., or about 100 deg. C. above the temperature required for the recrystallization of cold-drawn gold wires, a property he attributed to the absence of crystalline nuclei. It is now known that chemically precipitated metallic powders, even when composed of the finest particles, are perfectly crystalline, so that masses formed by compressing them are themselves predominantly crystalline.

It is quite certain that no totally amorphous mass of solid metal has been produced. A little consideration of the molecular structure of amorphous bodies is interesting in this connection. The materials which are most readily obtained in amorphous form, such as pitch, glass and vitreous silica, always have several atoms to the molecule. Some of the chemical elements, of which sulphur is an example, can also be obtained in an amorphous condition. A sulphur molecule contains eight atoms. Metals are monatomic in all conditions of aggregation and therefore crystallize more freely. A single atom can obviously find its place in a crystal lattice more easily than can a molecule containing several atoms. It will therefore be very difficult to obtain metals in an entirely amorphous solid state.

POSSIBLE STRUCTURES AT GRAIN BOUNDARIES

The best evidence for the existence of amorphous metal is probably to be found in the conditions at grain boundaries. In the original statement of their intercrystalline cement hypothesis Rosenhain and Ewen advanced the idea that the crystallization of metals takes place by the addition of crystal units containing large numbers of atoms. In the region where two crystals abut against one another—that is, at the grain boundaries—there would have to be some metal which could not attach itself to either crystal because of being too small in amount to form crystal units. Furthermore, since the crystalline grains have different orientations, the units or blocks of one would not fit

in with the blocks of the other, and interstices of irregular shape would be left which could not be filled up with other crystals no matter what their orientation. The metal remaining in these interstices must then retain the structure of the liquid—i.e., must be amorphous.

The diagram in Fig. 1 shows this condition in a schematic way, the shaded areas representing the interstices filled with amorphous metal.

This conception is no longer tenable, inasmuch as it now appears quite certain that the "crystal units" consist of one atom each. The actual conditions must nevertheless be very similar, in a qualitative way and on a smaller scale, to those represented in the diagram.

FIG. 1. HYPOTHETICAL CONDITION AT GRAIN BOUNDARY (ROSENHAIN AND EWEN²)

Certainly where two crystals of different orientation meet it is not geometrically possible for all of the atoms present to have places in an undisturbed space lattice without leaving some voids.

There are three possible conditions: (1) There are voids between the two crystals; (2) there is a zone in which some of the atoms are held in *both* crystal lattices, in which case the lattices would be distorted at the surface of contact; or (3) there is a zone of disorganized or *amorphous* metal.

There is no way known at present of determining the actual structure at the grain boundaries of metals. It is certain that, under various conditions of temperature and rate of loading, metals behave as they would if their grains were held together by a cement of a substantially amorphous nature. There are many other properties of metals which are consistent with the assumption of an amorphous cement, and none, to the author's knowledge, which are inconsistent. The hypothesis is thus plausible from the structural viewpoint and logical in that it offers satisfactory explanations of the properties of the grain boundaries of metals. This is enough to justify the utilization of the idea as a working hypothesis—but we can go even further. The amorphous metal cement hypothesis is at the present time the *only* satisfactory explanation of the effect of temperature and rate of loading on the strength and manner of rupture of metals. This fact confers upon it an added degree of probability.

IMPURITIES AT BOUNDARIES

The only alternative theory that has been advanced is based upon the assumption that even in what are ordinarily termed "pure" metals there are appreciable quantities of impurities forming eutectics melting below the melting point of the metal. When the metal is heated to high temperatures, these eutectics melt and

form molten layers around the grains of solid metal. The molten layers have very little strength and hence allow the grains to be pulled apart on the application of small loads. There are a great many objections to this explanation. The phenomena to be explained occur with great distinctness in metals of the very highest purity. Any eutectic that might be present in such a pure metal would necessarily have a very high melting point, little short of that of the theoretically pure metal. In any case the melting point of the eutectic would be *fixed*. This is not the case with the temperature separating intergranular from transcrystalline fracture, which varies with the rate of loading or duration of load. Furthermore, intergranular fracture can be produced at any temperature from the recrystallization temperature to the melting point. The intergranular eutectic hypothesis is untenable from this point of view. An additional objection is that it does not sufficiently explain the time effect, especially on the tensile strength such as quoted on p. 699 for copper.

In the authors' opinion it is justifiable to conclude that the metal at the grain boundaries is or simulates an amorphous material. It is not possible to reach any definite conclusions regarding the degree of disorganization of this material or the thickness of the films around the grains. Although definite information on these points is desirable, it is not necessary to the formulation of a useful theory. The essential fact is that the grain boundary metal possesses mechanical properties like those of a vitreous amorphous substance.

The amorphous cement occupies a very important place in the structure of metals, inasmuch as it is continuous. Nevertheless, the amount of crystalline metal is so preponderant that as a rule metals never exhibit properties like those of an entirely amorphous material. In the tests of metals at high temperatures which have

FIG. 2. EFFECT OF RATE OF LOADING ON ZINC-ALUMINUM-COPPER ALLOY (ROSENHAIN, HAUGHTON AND BINGHAM)

been referred to, the tensile strength varies with the rate of loading in the same manner as that of an amorphous material. That is, the longer the time taken in breaking the specimen the smaller the load required. The elongation, on the contrary, follows an exactly opposite course. Metals broken by small loads acting for long periods of time show little if any elongation while an amorphous material like pitch or glass (at a red heat) shows more elongation the slower the loading.

ZN:AL:CU ALLOY OF PECULIAR PROPERTIES

An alloy has recently been described which is of special interest for the reason that both its strength and its ductility are affected by the rate of loading in

the same manner as are those of amorphous materials. The alloy is the ternary eutectic of zinc (89 per cent), aluminum (7 per cent) and copper (4 per cent). The principal metal, zinc, recrystallizes at room temperature so that the "high-temperature" phenomena of less fusible metals like iron are in this case obtained at ordinary temperatures. The properties are shown best by the alloy after it has been subjected to considerable rolling at about 250 deg. C. A strip of the metal in this condition can be bent double between the fingers, if the bending is carried out slowly, taking, say, five minutes. An attempt to bend the strip quickly causes it to break

FIG. 3. RETURN FLOW OR CREEP IN RECENTLY DEFORMED ZINC-ALUMINUM-COPPER ALLOY, PITCH AND GLASS (ROSENHAIN, HAUGHTON AND BINGHAM⁷)

with a sharp snap. This is exactly the behavior that would be expected of an amorphous material like pitch. This simple experiment demonstrates in a qualitative way the effect of rate of loading on the properties of this alloy. A quantitative expression of the same effects is found in the curves reproduced in Fig. 2.

This alloy resembles amorphous materials in another respect—namely, the return flow or "creep" after deformation. If a strip of amorphous material like pitch is bent in a given direction and then released, it springs back somewhat in the opposite direction, but does not immediately assume a stable position. It continues to creep back slowly at a steadily diminishing rate. All metals with the exception of single crystals behave in a similar manner, but the creep is usually so slight that rather sensitive instruments are required to detect it. Rosenhain's alloy exhibits this property to a degree comparable with pitch. The curves in Fig. 3 show the return creep for three materials, plotted to the same scale except that for glass the deformations are magnified $14\frac{1}{2}$ times.

The exceptional degree to which this alloy resembles materials that are entirely amorphous is attributed by the present authors to a very fine grain size stable at temperatures normally in the recrystallization range. The alloy consists of the three structural constituents of the ternary eutectic. These crystalline constituents are divided very finely by the rolling process. Grains of a pure metal broken up in this way by deformation carried out above the recrystallizing temperature promptly unite so that the metal is left in a moderately coarse-grained condition. In this case, however, the eutectic constituents cannot unite, and by interfering with grain growth in the matrix (zinc) cause the final grain size to be very small. This, coupled with the probable high specific hardness of the crystalline constituents, accentuates the effect of the properties of the grain boundary metal. The discovery of the properties of this alloy is important, because this is the

only case on record in which the properties of the amorphous "phase" completely mask those of the crystalline constituents in a metallic aggregate.

OTHER PROPERTIES OF GRAIN BOUNDARIES

There are many phenomena for which the amorphous metal cement hypothesis furnishes a convenient explanation, but for whose explanation the assumption of an amorphous cement is not necessary. They are therefore not to be regarded as strong evidence for the existence of an amorphous metal cement, but merely as facts which are consistent with the hypothesis. One group of such facts may be comprised in the statement that the grain boundaries of metals are particularly subject to chemical attack and to the penetration of gases. A bronze can be disintegrated into its individual crystals by the action of mercury (Desch),⁸ which dissolves away the grain boundary metal. Dickenson⁹ has shown that certain failures of manganese bronze were caused by the penetration of solder between the grains while the metal was under tensile stress. The solder must of course be molten to have this effect. It is usually necessary in this as in other cases of a similar nature for the metal to be under tension in order for any rapid intergranular penetration to take place.

Cold-worked articles of brass, such as cartridge cases, are subject to a type of failure known as "season cracking." After standing for some time, perhaps years, the article develops cracks which are shown by microscopic examination to be intergranular. It has been shown that season cracking can take place in the entire absence of corrosive agencies. There is no doubt, however, that corrosion either by the atmosphere or by other agencies greatly hastens the process. Brass articles are often tested for susceptibility to season cracking by immersion for a short time in a solution of mercurous nitrate. Metallic mercury is liberated and penetrates the grain boundaries of the brass where tensile stress exists. Cracking then follows quickly.

In the carbonizing of steel the carbon penetrates by way of the grain boundaries. The penetration is probably largely due to an actual penetration of carbon monoxide gas, although it is partly due to diffusion of carbon from the surface. This diffusion also follows the grain boundaries, as can be seen by reheating a graphitized iron to temperatures above the critical and then cooling rapidly.¹⁰ The carbon will be found to have been reabsorbed into the iron by way of the grain boundaries.

Commercially pure copper is embrittled to a ruinous extent by annealing in a reducing atmosphere, such as hydrogen. The hydrogen is supposed to penetrate the metal and reduce the copper oxide which is always present. The steam formed is unable to escape and its disruptive force is the cause of the bad effect on the copper. In this case again the penetration of the hydrogen takes place partly by way of the grain boundaries.

Many other examples could be cited to illustrate this susceptibility of the grain boundaries to attack. It is to be assumed that the amorphous cement supposed to exist at the grain boundaries is electro-positive to the crystalline metal, since it more closely resembles the liquid in structure and therefore has a higher internal energy content. This would account for its greater susceptibility to chemical attack and penetration by molten metals. The penetration by gases would be ascribed to the freedom of motion of the atoms in the amorphous metal, which would not present a rigid

barrier to the penetration of gas molecules as would the fixed atoms in the crystal lattice. These facts can also be explained on the assumption that the structure at the grain boundaries of metals consists of two perfect crystal lattices interlocking with the formation of voids free from any amorphous metal.

"VACUUM ETCHING"

Another phenomenon closely allied to these is one known broadly as "vacuum etching." Rosenhain and Ewen sought to demonstrate the existence of amorphous metal at the grain boundaries by determining the relative losses in weight of coarse- and fine-grained metals when heated in vacuo. They showed that the losses of the fine-grained specimens were much greater than those of the coarse-grained specimens, and attributed this to the presence of greater quantities of amorphous metal, which is quite logically supposed to have a higher vapor pressure than the crystalline metal. These observations are, however, explained with equal satisfaction on the basis of any of the three possible grain boundary structures mentioned above.

Special attention has been called by one of the authors¹¹ to the flow of metals at high temperatures. In making filaments for certain classes of electric lamps, it is desirable to have tungsten wire which will not sag under its own weight when heated to high temperatures. It has been found that at high temperatures fine-grained wires sag much more than do coarse-grained wires. This is consistent with the theory that the sagging consists in *flow* in the layers of amorphous cement around the grains. Small grains would lead to greater flow because of more grain boundary surface. An alternative explanation is that the sagging of the wires consists in a migration of the grain boundaries—that is, grain growth—under the influence of stress and temperature. Such grain growth would take place in a direction tending to relieve the stress, which would cause the wires to sag. The greater sagging of the fine-grained wires would be due to the greater boundary surface and to the greater tendency of small grains to grow. It is probable that this is a factor in the observed flow (although not the only one), but such a mechanism does not account for the strength properties of the grain boundaries. The authors therefore prefer to consider that the grain boundaries are amorphous, because this accounts for all of the observed properties.

AMOUNT OF AMORPHOUS METAL PRODUCED BY COLD-WORK

The question of the formation of amorphous metal during plastic deformation is perhaps more difficult than that of its existence at grain boundaries. There is again no direct evidence and there are in this case no phenomena which cannot be explained without assuming the formation of amorphous metal on all of the slip planes. Beilby advanced his hypothesis primarily as an explanation of hardening. It is the opinion of the present authors that hardening can be satisfactorily accounted for on the basis of a rearrangement of crystalline material, as described in a previous article.³ Any amorphous metal formed would of course contribute to the hardening, but it is not necessary to assume its presence for this purpose.

Beilby's hypothesis was, as indicated above, based largely on his studies of polished surfaces. Having concluded to his satisfaction that the surface layers of

polished metals are in an amorphous condition, he assumed that the internal friction on slip planes during deformation also generates layers of amorphous metal. There is some doubt that the surface layers of polished metals are entirely or even largely amorphous, but even granting that they are entirely amorphous, this cannot be considered as more than a suggestion that similar layers are formed on the internal surfaces of slip. The processes—polishing and slip—differ in two important respects. The friction in polishing is between the metal and a dissimilar surface, usually a cloth charged with fine particles of hard metallic oxide. Secondly, the amount of relative motion between the two surfaces in the case of polishing is enormously greater than in the case of crystalline displacement by slip.

BEILBY'S ORIGINAL HYPOTHESIS IMPOSSIBLE

A rough calculation will suffice to show that Beilby's hypothesis as originally proposed is impossible. According to this hypothesis, as well as the ideas prevailing among its adherents in England and America at the present time, amorphous metal is developed at *each* slip plane and slip occurs only *once* on each plane. From many observations of slip bands, made mostly on fairly coarse-grained specimens, it appears that the maximum extent of motion along a slip plane during a single deformation ranges from 1,000 to 5,000 atom diameters, seldom greater. It also appears that the extent of slip is less the smaller the grain size. Normally, therefore, the average extent of a single slip is probably well under 1,000 atom diameters. Assume, for example, a single crystal in the shape of a 1-in. cube, of a metal having 100,000,000 atoms per linear inch. Assume that slip generates amorphous layers two atoms in thickness, which is about the minimum that could be considered amorphous. The number of possible slip planes on the cross-section would then be 50,000,000. A slip on each of these planes to an extent of 1,000 atom diameters would result in a general extension of 500 in., after which all of the metal would be amorphous.

But copper can be extended by cold-swaging and drawing, without intermediate annealing, to as much as 5,000 times its original length and the metal is still preponderantly crystalline! Tungsten wire drawn to 200,000 times its original length without intermediate annealing still gives perfect X-ray patterns, showing that it is predominantly crystalline! Beilby's scheme of plastic deformation is not consistent with such facts.

The wires of copper, silver and gold with which Beilby experimented were in no case drawn to more than fourteen times their original lengths, and he stated that the maximum strength was reached after drawing to from three to five times the original length. This increased strength and hardness he attributed to the formation of layers of amorphous metal, yet the proportion of metal converted to the amorphous condition would not have to be so very large. The greatest possible proportion actually so converted in his wires may be judged by the fact that wires drawn one thousand times as much are still predominantly crystalline. We believe, therefore, that any amount of amorphous metal that may be produced by drawing a wire to five times its original length could not in itself be responsible for the increased hardness and strength.

The abundance of crystalline material left in a cold-drawn wire is further shown by the fact that wires drawn until they have lost practically all of their ductility when tested at ordinary temperatures regain their

ductility to a large extent on cooling to the temperature of liquid air. Ductility is at low temperatures dependent on the presence of a very considerable amount of crystalline metal, since amorphous metal is considered to become increasingly hard and brittle as the temperature is lowered.

The evidence shows that whatever amorphous metal may be formed during cold deformation is very much less in amount than indicated by Beilby and generally held by the adherents of his hypothesis. It follows that the importance attached to the specific hardness of amorphous metal as the cause of hardening has also been greatly exaggerated.

WHAT CAUSES A SLIP TO HALT?

The conclusion that there are not formed on *all* of the surfaces of slips vitreous amorphous layers which prevent further slip on those surfaces does not preclude the possibility that some amorphous metal is produced during plastic deformation. A little consideration will show us that the block movements on slip planes, or "slips," may be divided into two rather distinct classes.

When a single crystal of metal is broken in tension, it might be expected that the final failure would take place on the first plane on which slip occurs. Such, however, is not the case, since large single crystals of ductile metals are themselves ductile and draw out under tension into the form of wedges. This shows that failure does not occur on the first slip plane. We must conclude that something happens during the process of slip which causes the resistance to further slip on that plane to be *greater* than the resistance to the starting of slip on some new plane. The slip may be said to be "self-stopping."

In ordinary pieces of metal which are aggregates of many small grains it is probable that only a small proportion of the slips are self-stopping. The majority of the slips are brought to rest by end resistance. There is every indication that the resistance to further movement on the surfaces of such slips is *less* than the resistance to the starting of slip on a new plane. At the beginning, therefore, a slip plane is a surface of weakness.

All this amounts merely to saying that a certain amount of *movement* or of *time*, or both is required for the building up of resistance on a slip plane. The "weakened and building-up" stage corresponds to the "mobile" state of Beilby. It may be that amorphous metal is actually in process of formation in this stage. The later stage when the slip has become self-stopping undoubtedly represents an altered structural condition at the surface of slip, which must necessarily involve some local disorganization of the crystalline metal. This disorganization may or may not be sufficient in kind and depth to justify the assumption of *vitreous* amorphous layers. The indications are that the disturbance does not penetrate very deeply and also that the differences in orientation between two adjacent crystal fragments are never very great. *Certainly the surface condition at slip planes even in the self-stopping stage does not prevent further movement on the same surface.* In the first stages of slip there is no reason to assume the presence of any amorphous metal, and in the later stages it is not justifiable to assume the presence of vitreous layers so rigid as to prevent further slip.

At the grain boundaries the conditions are different. The shapes of the original grains must change in a manner depending on the change in shape of the piece

of metal taken as a whole. No matter what the direction of extension, the grain boundary surface is increased by cold-work. Each slip intersecting a grain boundary produces one "lapped-over" fragment the surface atoms of which may be utilized to increase amorphous metal at the grain boundary. As deformation becomes severe, the grain boundary layer of amorphous metal should become thicker by the same process. It is the authors' opinion that the chief generation of amorphous metal by cold plastic deformation occurs here.

SUMMARY

1. Certain properties of cast metals or metals which have been worked and annealed are satisfactorily explained only on the assumption that the metal at the grain boundaries is in a substantially amorphous condition.

2. There is not at present sufficient evidence to determine whether this grain boundary metal possesses the perfectly amorphous structure indicated by the term *vitreous*. There is, however, enough evidence to justify the assumption that the grain boundary metal possesses the essential deformational and strength characteristics of typical vitreous amorphous materials.

3. The hypothesis that crystalline grains of metal are cemented with amorphous metal—i.e., the amorphous metal cement hypothesis—is not inconsistent with any of the known properties of metals.

4. Plastic deformation at temperatures below the temperature of recrystallization generates additional amorphous metal at the boundaries of the original grains.

5. There is no means of estimating with any exactness the quantities of amorphous metal which may be present under various conditions. There is certainly more amorphous metal in severely cold-worked metals than in annealed metals. Even the most severely cold-worked metals are predominantly crystalline. The amorphous metal hypothesis is a qualitative rather than a quantitative conception, so that it is perhaps not necessary to form very definite ideas as to the possible quantities of amorphous metal.

6. The formation of vitreous amorphous metal at all the internal surfaces of slip in the manner postulated by Beilby is not possible, and the hardness produced by cold-working can be readily explained without the assumption of such amorphization.

7. There is developed on some of the surfaces of slip a condition of cohesion greater than that in the undeformed crystal. This condition may presumably be due to a locally disorganized structure, but the assumption of a layer of *vitreous* amorphous metal is not necessary nor is it consistent with all of the facts.

8. Whereas the amorphous metal theory of deformation postulates that when slip has once occurred on a particular plane, no further slip on that plane is possible, the evidence available indicates not only that further slips on a "used" plane are possible but that they *must* occur in the course of the maximum deformation that can be effected.

9. The conception of an intergranular amorphous metal cement furnishes a very good explanation of certain deformational and strength properties of metals and a very useful working hypothesis. The importance attached to the specific hardness of amorphous metal as a cause of hardening has been greatly exaggerated.

Volumetric Measurements of Pulpwood

In making pulpwood measurements and yield determinations it is often desired to ascertain the solid contents of a piled cord. The apparatus used for that purpose at the Forest Products Laboratory consists of (A) a galvanized tank set in the ground, with a volume of about 1.75 cu.ft. per ft. of length; (B) a tripod placed over the tank for raising and lowering the heavier sticks; (C) a glass gage on the side of the tank, calibrated to read in cubic feet and decimals thereof; and (D) a simple vernier scale attached to the glass gage to permit closer reading to five thousandths of a cubic foot. Ten divisions on the vernier equal nine divisions

on the stationary scale. Graduations on the stationary scale are in tenths and five hundredths of a cubic foot.

Before immersing each stick, the water level in the gage should be at or slightly above the zero mark. The stick is immersed and held just below the surface of the water by a pointed rod stiff enough to overcome the buoyancy of the largest and driest pieces without bending. One gage reading is made before and one during the immersion of the stick, the difference giving its volume.

The Fine Art of Lime Burning*

Complete Mechanical Handling of All Materials and Precise Technical Control of All Operations Have Been Provided For in the New Plant of the Rockland & Rockport Lime Corporation
—Crushing Plant—Kilns—Charging Equipment—Storage and Packing

BY GEORGE B. WOOD†

EACH individual limestone requires its own peculiar heat-treatment to produce a lime of desired qualities. A certain limestone, for example, may best be hard-burned slowly at low temperature for furnishing lime to a causticizing plant. It may best be light-burned at low temperature for building lime and it may best be light-burned quickly at high temperature for lime to go to the hydrating plant.

Dr. Holmes, of the Lime Association, is undoubtedly going to discover a lot of valuable truths along these lines, but such knowledge will profit us little until we build lime-burning plants capable of operating under stabilized conditions of physical and chemical control.

With these requirements in mind, as well as maximum heat efficiency and minimum labor operating costs, what should we demand of the modern limekiln?

1. Continuous mechanical feed of rock and continuous mechanical discharge of lime. When lime is properly burned it should be immediately taken away, not left to soak in the heat and gases for four to six hours.

2. Positive control of temperature.

3. Positive control of draft.

4. Positive control of burning period and lime discharge.

5. Positive control of combustion.

6. Minimum temperature of flue gases and cool lime ready for immediate handling and shipment as it leaves the kiln.

The new plant at Rockland, now nearing completion, is capable of meeting all of these requirements and based on the results of an accurate test with our stone will undoubtedly show a saving of 50 per cent in labor cost and very probably a saving of 50 per cent in fuel consumption over the former old-fashioned methods with hand-fired kilns.

ROCK-CRUSHING PLANT

The first requirement for maximum efficiency and uniform quality is uniform-sized stone going into the kiln. Our new rock-crushing plant at the quarry (Fig. 1) is not unique in any particular feature except for provision in the storage bin of three separate compartments, making possible three different classifications of quality of rock going to the kilns. The plant consists of a 48 x 42-in. Traylor jaw crusher set entirely below grade, permitting a trainload of rock (twenty-five to thirty 4-yd. standard-gage dump cars) to run down by gravity, dumping one car at a time into the crusher. An air hoist facilitates dumping of cars and an electric car puller starts the train whenever cars fail to move by gravity. Each car holds between 5½ and 6 tons of rock, and we recently dumped through the crusher as a

test twenty-five cars in 22 minutes. A pan bucket elevator 84-ft. centers with buckets 42 in. wide carries the rock to the top of the structure, where a shaking grizzly separates the 3-in. and smaller stone from the kiln stone. A revolving screen and a small auxiliary gyratory crusher sizes small stone for the crushed stone market. A 14-in. belt conveyor 100 ft. long, discharging into an abandoned quarry, disposes of the surplus fine stone when there is not a market. This spill conveyor

FIG. 1. ROCK-CRUSHING PLANT

eliminates all the additional handling cost in winter time from small stone frozen solid in bins and cars. The storage bins hold a total of 900 tons of the various sized stone and discharge from the bottom and the side into cars on two loading tracks. All machinery is electrically driven.

LOCATION AND SHIPPING FACILITIES

The kilns, hydrate mill, barrel factories and warehouses are all located at the waterfront of Rockland harbor, and the quarries are situated a mile and a half inland. The lime company owns and operates a standard-gage steam railroad, a belt line around the city which is a switching terminal and feeder for the Maine Central R.R. Coal and cooperage stock are received by water, lime is shipped by both rail and water and the Lime Rock R.R. distributes rock and coal and handles all the freight cars for the various plants. The railroad has 13 miles of main line and sidings, four locomotives and 495 4-yd. dump cars which are maintained and repaired in the company's own shops.

With this explanation of plant conditions, it will be understood why we have adopted at the new kiln plant a rather new and unusual method of rock storage and kiln-charging machinery.

LIMEKILNS

The new lime plant comprises a battery of six Mount kilns with two Morgan mechanical producers centrally located and one horizontal tubular boiler. The plant is

*Paper presented at the third annual convention of the National Lime Association, New York, June 16, 1921.

†President, Rockland & Rockport Lime Corporation, Rockland, Me.

FIG. 2. GENERAL ARRANGEMENT OF LIME PLANT

designed with provision for two additional kilns at either end to make a future battery of ten kilns. The ultimate extension of the plant is indicated in Fig. 2. The boiler is fired with producer gas, but the setting provides for a mechanical coal stoker to be installed in the future when ten kilns are put on the two producers.

The kilns (see Figs. 3, 4 and 5) are 10 ft. outside diameter and 75 ft. high above foundations. The brick lining stops at a height of 55 ft., where the gases are drawn off by induced draft through waste gas flues leading to a duplicate system of motor-driven exhaust fans. The top 20 ft. of the kiln is unlined and holds a reserve storage of 45 tons of rock. The rock is charged through an air-tight charging bell at the top of the kiln, which is operated by compressed air. The draft of each kiln is regulated from the floor by a cable leading to a damper on the exhaust flue. Water-cooled valves regulate the flow of gas through tuyères on two opposite sides of each kiln. Constant gas pressure is maintained at the producers by automatic regulators. Air for combustion is drawn from the bottom of the kiln through the hot lime below the fires, preheating the air before meeting the gas for combustion and thoroughly cooling the lime before it discharges from the kiln.

The lime discharges continually through an annular opening at the bottom of the cooling cone onto a slowly revolving circular table. The speed of the table determines the rate of discharge and may be regulated for each kiln independently through the simple shift of a lever. A 24-in. steel pan conveyor receives the continuous discharge of lime from all the kilns and carries it into the lime sorting and packing building.

The coal arriving at the plant is dumped from cars into a track hopper, where it is crushed and elevated by machinery into a 100-ton storage bin over the gas producers. The producers are fed and poked mechanically and also by machinery discharge their ashes at fixed intervals into cars spotted on a depressed railroad track which runs through the kiln building. Soot traps in the main gas flues also empty direct into cars on this track.

TEMPERATURE CONTROL OF KILNS

Each kiln is fitted with two pyrometers, one at the high-temperature zone and one at the top. A cabinet at each kiln contains the indicating instrument with a two-way switch as well as a draft gage permanently connected to the kiln. The high-temperature pyrometer of each kiln is also permanently connected by special cable to graphical recording instruments located in the superintendent's office. Thus the foreman on duty can at all

times note the temperature and draft readings of each kiln and make adjustments to maintain predetermined continuous operating conditions. Also the superintendent may look at the six continuous red ink lines on the chart in his office and know without doubt if the temperature went wrong on any of the kilns during the day or night.

TECHNICAL CONTROL OF KILNS

Here is the time to introduce the plant chemist and his three assistants, perhaps more properly termed chemical engineers. The assistant chemist on duty through an 8-hr. shift will be the cock of the walk. At fixed intervals he makes quick analyses of producer gas and flue gases, notes the kiln temperature and the lime and knows without guesswork what to do. By his

FIG. 3. MOUNT KILN IN SECTION

orders the boss kiln tender closes a gas valve here, opens a draft damper at some other kiln, speeds up the discharge of one kiln or slows down another. Again he may order the producer operator to speed up the coal feed on No. 1 producer or open the air damper on the blower of Producer No. 2. If draft conditions and flue gas analyses persist in acting queerly on Kiln No. 5, we may find the assistant chemist and the kiln boss looking

in the observation ports and finally discovering on the operating platform at the third level that the kiln is hung up on one side and must be barred down immediately.

Here, then, is a kiln plant that can almost talk if it is treated in the manner which it deserves.

Let us suppose there is a periodic shortage of cars, the lime bins are nearly full and we must slow up production. With this plant the temperature may be lowered and the discharge slowed down to operate the whole plant at one-half production. The lime may be somewhat different from that burned at high temperature, but it will be good lime, not like some we used to get when we had to plug the old-fashioned kilns. When

FIG. 4. KILNS UNDER CONSTRUCTION

cars come again in two days the young assistant chemist orders the temperature up, the drafts brought back and then the lime discharge gradually increased until early in the afternoon the plant is again in full swing at maximum production. Perhaps, however, just to romance a little, Kiln No. 1 is still kept at lower temperature because that kiln is filling an order for lime to the toothpaste trade and Dr. Holmes has very definitely determined that lime for this use should be burned under such conditions.

CHARGING KILNS

We will now go outside the kiln building and observe the method of charging rock into the kilns. This feature is perhaps the most unusual part of the new plant design. Consideration has been given to the fact that this plant is located near the residential section of the city and therefore in addition to no smoke there must be as little noise as possible, particularly during the night. Large rock storage provided at the kilns overcomes a temporary breakdown on the railroad system and the kiln-charging mechanism is designed for a ten-kiln plant with capacity to charge 700 tons of rock within an 8-hr. workday. The rock arriving in trainloads at the kilns is dumped from an overhead trestle into a side hill storage extending the full length of the kiln battery and capable of storing in the neighborhood of 3,000 tons. A concrete base and wooden bulkhead with discharge gates for each kiln forms the front wall of this continuous storage bin. Between this bulkhead and the kilns is located a traveling skip hoist (clearly shown in Fig. 5), which acts as a single mechanical charging machine for the entire battery of kilns.

This is a steel structure 105 ft. high, the base measuring 34 x 26 ft., counterweighted with concrete and supported on car wheels which travel on 80-lb. railroad rails. Electric hoisting and haulage engines, with automatic control, are located in a steel house on the base of the structure and power is taken from trolley wires attached to the kiln building. Two skip cars hung in balance travel on separate rails to the top of the structure, where they dump automatically into a common receiving bin discharging into the rock hopper of the kiln. Operation is entirely automatic from push button control. The operator on a platform at the base of the structure opens a rock gate and fills the skip on his right with 3 tons of rock, closes the gate and pushes a button. The skip travels to the top, dumps and stops, bringing the second skip to the bottom opposite the gate on his left. The operator fills the second skip, again pushes the button, and so continues until the kiln is filled. He then takes the handle of a controller and moves the whole structure as a motorman moves his trolley car along the rails, until it comes abreast the next kiln and another pair of gates in the rock bin. One man operating the machine and one man at the top of the kilns will constitute the labor necessary at the kiln plant to put 700 tons of rock into ten kilns. The machine will ordinarily travel the length of the row of kilns filling them in the morning and repeat the operation in the afternoon. The storage magazines in the kilns will keep them fed with rock from that time until the next morning.

The mechanical draft and mechanical operation of these kilns make it possible to burn the smaller sizes of stone from the quarry. This is true particularly with stone which does not fine up in burning, and we expect to be able to burn our Rockland stone in sizes down to as small as 2 in. If practical operation proves it advisable, the stone can be classified at the crusher plant and

FIG. 5. TRAVELING SKIP HOIST FOR CHARGING KILNS

bin partitions provided at the kiln storage, making it possible to run certain kilns independently on certain sizes or certain quality of stone.

This completes the details of the lime-burning plant and we will now follow the lime on its course into the storage and packing buildings. Here we see how simplified the process may be when lime comes continuously and cool from the kilns instead of by periodic batches drawn hot onto a floor or into bins to cool.

The storage and packing building is a two-story fire-proof steel structure 108 x 60 ft. and adjoining the kiln building. As the lime conveyor enters this building it rises and discharges the lime over a bar grizzly, separating it into fines and lump deposited respectively onto two parallel pan conveyors which are elevated 3 ft. from the floor and act as a sorting table.

Here will be stationed one man on continuous duty for each 8-hr. shift, sorting into selected lump lime and common lime quality. The larger lumps are broken to remove possible core, black lime or possible brickbats are discarded and second quality lump lime is transferred from the selected side to the common lime side of the sorting table.

These conveyors discharge into bucket elevators, which carry the lime to the top of four overhead steel storage bins, each with a capacity of 500 tons. Two of these are shown under construction in Fig. 6. The storage bins are cylindrical, 25 ft. in diameter, with cone top and bottom. Special gates and shaking chutes discharge from the bins through the side of the building,

FIG. 6. LIME-STORAGE BINS

loading directly into box cars with a Pratt box car loader or directly into dump cars to go to the hydrate mill. Each bin has two barrel-filling chutes so designed that the operators may sort the lime as packing. This makes possible a second inspection of all lime filled into barrels.

The second story of the building is for empty barrel storage where one or two men are on duty to receive and pile new barrels from the barrel factory and to pass them into the feeding chutes leading to the lime packers on the lower floor. The lime packer takes each empty barrel from the chute, like taking a paper drinking cup, and fills it to required weight on a specially fixed counterweight scale. Trimmers put in the heads and trim the barrels and stevedores truck it direct into cars which may be spotted on railroad tracks at either side of the building. All lime will be packed only for immediate shipment except when anticipating rush shipments such as 7,000 large barrels to be loaded into a barge cargo for the New York market or 2,000 small barrels for a schooner shipment to Boston.

In such cases it is possible to store on the floor of the packing house 2,500 barrels at a time. Provision is being made to install at a later date a slow moving conveying platform which is level with the floor and follows a continuous rectangular course around the cen-

tral storage area. The man at the chute will fill a barrel with lime and place it on the moving platform, which immediately takes it out of his way. The trimmers will head up the barrels on the platform as it travels along and eventually the finished packages reach the desired place where they may be put directly into a car for shipment or onto the floor for storage.

Excepting the cases of emergency shipment, all packing and shipping will be daytime work six days a week. On Sundays and nights the lime goes into storage, the only men on duty being the eagle-eyed inspectors at the sorting table. There should be no loss from old lime air-slaking in barrels, and with storage capacity in air-tight bins for 2,000 tons of lime, the normal fluctuations of market demand should be discounted, making possible more uniform capacity operation of the kilns. All machinery is electrically driven with power bought at 2c. per kw.-hr. All the lime, coal and rock handling equipment was designed and furnished by the Link Belt Co.

Chemical Industry Power and Fuel Data

BY H. GOODWIN, JR.

THERE has recently been completed and shortly there will be issued the Report of a Superpower System for the Boston to Washington region. This has been made under the U. S. Geological Survey to determine the feasibility and economy of a "superpower" electrical system proposed to supply power to all at reasonable rates and to use waterpower to the fullest extent, by these two means conserving the nation's fuel resources.

The Bureau of the Census has co-operated in this by supplying data from the 1919 Census of Manufactures (soon to be published) prepared in a new and special form to facilitate analysis of the power and fuel requirements of each industry. The accompanying figures for the chemical industry will serve to supplement the general data given on p. 470 of the Sept. 7 issue.

POWER AND FUEL USED BY CHEMICAL INDUSTRIES

Table I gives a summary of the power and fuel used by the chemical and allied industries in the "superpower zone." The divisions are quite clear, but a few of the industries included under "all other chemicals" might be mentioned as follows: Acids, drugs, dyestuffs, fertilizer, ink, oils, paints, salts, soap, etc.

The column headings are self-explanatory except the next to the last column. On account of the great variations in the proportions of anthracite and bituminous coal used in the different industries, it was necessary to reduce them to common terms for comparative purposes. Most of the anthracite used is in the small sizes with low heating value. Further, boiler efficiencies are lower with anthracite than with bituminous coal. So it was determined that 1 long ton of anthracite as used in the industries is equivalent to 1 short ton of bituminous, and conversion was made accordingly to arrive at the total.

The total fuel used by all the manufacturing industries (excludes electric central stations, residences, etc.), in the "zone" was 53,463,513 tons, compared with 11,986,628 for the chemical industries, showing that the latter account for 22 per cent of the total fuel within the zone. But 7,500,000 tons are used in the manu-

TABLE I. SUMMARY OF POWER AND FUEL USED BY CHEMICAL AND ALLIED INDUSTRIES IN SUPERPOWER ZONE

Group	Data from 1919 Census of Manufactures						Fuel Used

Petroleum refining.....	21	21	3,167	66,517	65,020	1,497	1,037,653	388,913	1,322,800	222,156
All other chemicals.....	2,937	1,853	156	289,867	184,965	104,902	993,197	1,956,813	2,850,695	39,840
Total.....	3,256	2,109	248	523,849	390,558	133,291	3,304,186	9,016,295	11,986,628	907,570

facture of coke and gas, being largely converted into other forms of fuel. This leaves 4,500,000 used for power and process purposes in the other chemical industries, and this is 8 per cent of the grand total. So the place of the chemical industries in any fuel program is most important.

The total aggregate power used by all the chemical industries is 523,849 hp., which is approximately 6 per cent of the 9,069,471 hp. used by all the industries in the zone. The average size of the plants in this industry is large, 248 hp., as compared with 119 hp. for all industries.

DISTRIBUTION BY SIZE OF PLANT

Table II shows the special details for the analysis of the general chemical industry ("all other chemicals" of Table I). The same column headings appear here, considerably expanded, but all are self-explanatory. Particular attention is directed to the first two columns, as these show the special and unusual features of the

tabulation. There are four main groups, establishments using: (1) No power, (2) steam power only, (3) purchased electrical power only, (4) all other power. Each of these main groups (except "no power") is subdivided by plant size into three groups, 200 hp. and 500 hp. being the dividing lines. These groups and sub-groups are carried through all the power and fuel items. Thus there is given for each size plant and character of power supply the total power and the fuel associated with its use. The greater fuel economy of the plants purchasing power is evident, but on account of the varied nature of the processes involved conclusions are somewhat limited. However, the large use of live steam in chemical plants with independent development of power would appear to confirm the great economy of purchased power shown.

The Superpower Report will show detail tables for over fifty industries, and the system proposed will provide a convenient reliable source of power for the proper electrification of all industries.

Coking Mid-Continent Coals*

DURING the latter part of 1917 the attention of the Department of Commerce was directed to the Roberts coke and gas oven through the efforts made by the American Coal & By-Products Coke Co. to obtain Government support for this enterprise. This matter was referred to the Bureau of Standards for action.

The promoters of this process claimed a number of advantages for this oven which it was said were not embodied in other types. Among these were the following: (1) Ability to coke so-called non-coking coals

FIG. 1. GENERAL VIEW OF THE DOVER BYPRODUCTS CO. PLANT

and produce a satisfactory grade of metallurgical coke from high-volatile mid-continent coals; (2) larger yields of byproducts recovered than from other types of ovens; (3) more substantial construction than possible with existing types of ovens; (4) greater degree of flexibility of heat control than with existing types of ovens; and (5) increased earning power per oven over the other types of ovens.

At this investigation it appeared that the ovens were operating in a fairly satisfactory manner, and although the bureau was not able to verify these claims to any great extent in such a short period, the indications were that the oven could be developed into a commercial success. Therefore the Bureau of Standards reported to the Assistant Secretary of Commerce on Dec. 15 as follows:

"We do not hesitate to recommend favorably this type of oven for further consideration, for we feel sure that benefit to the Government and the people may be expected from the commercial development of the process."

ADVISABILITY OF STUDYING THE COKING OF MID-CONTINENT COALS

In addition to the lack of coke-oven plants, climatic conditions during the winter months of 1917-18 greatly reduced the coal supplies of the existing plants. Transportation of large quantities of coal became increasingly difficult as the severe winter weather continued and as the railroads became choked with materials moving toward the seaboard. This particularly interfered in the maintenance of the production at full capacity on the part of the coke ovens in the central section of the country, since most of the existing plants in this section were dependent for their coal supplies upon so-called Eastern coal. Likewise, with the increase of

traffic more and more coal was used by the railroads and the use of raw coal in boiler plants and in other industrial activities, and in the heating of dwellings, factories, etc., due to the extreme cold and lack of other fuels, depleted the supply of fuels for these ovens.

Accordingly the utilization of much of the undeveloped fuel resources of the country became a question of paramount importance. Attention was forcibly directed to the large quantities of mid-continent coal available, particularly in Indiana and Illinois, but which was not being used. Inasmuch as the steel production of large plants, such as those at Gary, Ind., and Joliet, Ill., was sometimes reduced to 30 per cent through lack of coke, it was evident that some relief was essential.

Since it was claimed for the Roberts oven that it was able to produce a first-class grade of metallurgical coke from these mid-continent coals, it was natural that this type of oven should be looked upon as a proper agency to aid in the forestalling of the crisis which seemed imminent, as well as to assist in the development of these hitherto unused coal resources of the country. Therefore using the bureau's report of Dec. 15, Mr. Roberts endeavored to interest the Government in aiding in the further development of his process and to construct two plants, one at East St. Louis, Ill., and the other at Chicago, Ill., which would use coal from the Illinois (mid-continent) field, thus avoiding the long railroad haul and accelerating the production of coke, toluene, etc.

TEST CONDUCTED BY THE BUREAU

Since the Dec. 15, 1917, report of the bureau was only a recommendation for further consideration, early in March, 1918, the Secretary of Commerce, acting by direct instructions from the President, ordered the bureau to conduct an operating test of the Roberts oven installation at Canal Dover and to associate with itself the Bureau of Mines and the Geological Survey in this work. Accordingly plans were immediately made for

FIG. 2. PUSHER SIDE OF COKE-OVEN BATTERY

such a test, and representatives of the bureau proceeded to Dover on March 18, but found that it was not feasible to begin the test at the time specified owing to a lack of boiler capacity.

The ovens at Dover were operating at this time on Cambridge (Ohio) coal, which, although somewhat similar to the mid-continent coals, bears a striking resemblance to the Eastern coking coals.

It was decided, however, that the test should be conducted with the same coals which would be used at East St. Louis and Chicago; therefore the bureau was

*Extracts from miscellaneous publication 46 of the Bureau of Standards entitled "War Work of the Bureau of Standards." This represents the first public announcement of results of the investigation conducted during 1918.

instructed to assist in obtaining the necessary coal for this test, together with the required boiler parts. This the bureau proceeded to do, but, hindered by numerous construction and transportation delays, it was not until April 26 that the test was officially started.

Quantitative observations of all parts of the plant operation were undertaken and were continued twenty-four hours each day, including Sundays, until May 11. During this test 4,800 tons of Illinois coal was used in the ovens, and all of the usual byproducts, including light oil, ammonia and tar, were recovered and either carefully weighed or measured. The coal used was shipped from the Royalton, Sesser and Orient mines in Franklin Co., Ill., and the Ayrshire mine, Pike Co., Ind. This work was conducted by twenty-two representatives of the Bureau of Standards and nine members of the regular staff of the Bureau of Mines; five consulting engineers were also present at the request of the Bureau of Mines to advise concerning the work.

The bureau's representatives were in charge of the test and responsible for observations of all work done about the coke oven, the byproduct department, the light-oil department and the other accessory operations. Exact records were made of the charging and discharging of the ovens, the quantities of tar, ammonia liquor, light-oil (containing benzene, toluene, etc.), and gas produced during the test period. Samples of all these materials were regularly taken, and analyses or tests of these samples made at appropriate intervals. Likewise, high-temperature measurements at various parts of the battery were carried on during the test.

The Bureau of Mines was responsible for the sampling of the coal at the mines, as it also was for the sampling and analysis the coal as it was unloaded in Dover for the test, and for the sampling, weighing and analysis of the coke produced from the test coal.

Because of mechanical difficulties the regenerators were not used during the test; therefore the ovens were not operated upon pre-heated air, but upon cold air. This precluded the making of any surplus gas, as it was necessary to use all that was obtained in heating the ovens. Difficulty was also experienced in the uniformity of the heating of the oven walls, the ends particularly being noticeably cold.

RESULTS OF TEST AT DOVER

The coke produced from three of the test coals was satisfactory as to quantity and quality, the yield being substantially the same as that obtained from other byproduct ovens. On the basis of dry coal, the yield of dry coke was 69.5 per cent, and the percentage of the sizes of dry coke to total coke were furnace size 75.1, nut 16.8 and breeze 8.1 per cent. A sufficient amount of coke was not produced by the ovens to operate the 500-ton blast furnace adjacent to the plant without the use of additional coke from other sources. Since the furnace was not able to operate at more than three-fourths capacity and since the quantity of coke had to be increased by the addition of outside coke to the extent of from 30 to 50 per cent, it was impossible to determine the real metallurgical value of the coke. However, the opinion of the superintendent of the blast furnace was that when 100 per cent of this Illinois coke was used it would make a satisfactory blast-furnace fuel with the furnace at full capacity.

The yield of toluene both as to quantity and quality was good and amounted to about 0.43 gal. per ton of dry

coal, and the yield of benzene amounted to 1.55 gal. per ton of dry coal. The yield of other byproducts per ton of dry coal were as follows: Ammonium sulphate, 26 lb.; tar, 10.7 gal., and gas about 10,000 cu.ft. However, on the basis of the quantity of these materials actually in the gas, the yields were somewhat higher than those quoted.

CONFERENCE AT PITTSBURGH

After the test at Dover was completed, a conference, which was arranged by the Bureau of Mines, was held in Pittsburgh on May 22, and the observations and results of the tests were discussed at length. Substantial agreement was reached as to what had been demonstrated by the test and what the results signified, and a report of this conference was made to the Secretary of Commerce on May 25, which was signed jointly by the directors of the Bureau of Standards and the Bureau of Mines. The report was as follows:

The Roberts oven produced a satisfactory grade of metallurgical coke from three of the four coals used. These coals have not heretofore been used to make metallurgical coke in commercial quantities. The gross yield was substantially the same as that obtained by other byproduct ovens. The coke was mixed with about an equal amount of coke from other sources, because of the limited supply of Dover coke, and was used in a blast furnace running at about three-fourths capacity. A satisfactory grade of pig iron was produced. The superintendent of the furnace is of the opinion that he could operate satisfactorily with this coke alone and at full capacity.

The quantity and quality of the gas produced were good. After removing the byproducts all the gas was used in the process of coke making. An excess of gas will be available when regenerators are in successful operation.

The quantity of byproducts in the gas was good. The amount of tar, toluene, benzene, etc., in the gas was about the same as is obtained in other ovens when high-volatile coals are used and was greater than the average yields from low-volatile coal, or the usual mixture. The amount of ammonia in the gas was very good.

The construction of the ovens is substantial. The heating system of the Dover plant leaves something to be desired in the matter of uniform heating of walls, and the regenerators for pre-heating air have not been in operative condition. Experience with the plant shows it can be improved in some particulars, and the company believes successful pre-heating of air and uniform heating can be demonstrated in a short time. It was necessary to run the test without regenerators, and as their use is essential for most efficient operation under usual conditions and in normal times, this further demonstration is believed to be necessary.

The Roberts Co. immediately proceeded to carry out the agreed program for a further demonstration, but great mechanical difficulty was experienced in putting the ovens into shape for this purpose, and it was not until the latter part of September that it was possible to complete the work.

FURTHER WORK AT DOVER

Since the War Industries Board had requested that a complete operating test be made with mid-continent coal, 1,500 tons of Orient and 1,000 tons of Ayrshire coal were secured for this test, and arrangements made whereby the coke would be stored until a sufficient amount had been accumulated, so that the blast furnace could run for several days at full capacity on 100 per cent Illinois coke.

The test began on Oct. 12, with the same methods pursued as were carried on in the May test, but before evening on Oct. 14 the representative of the Roberts Co. requested that the demonstration be stopped, since the

quality of the coke and the condition of the plant showed that it was not possible to make a successful demonstration at this time. The bureau acceded to the request, and after conference with the War Industries Board decided that until the company could demonstrate that the Roberts ovens could coke 480 tons of coal per day, the bureau would not consider another test.

CONCLUSIONS

From the investigation of these subjects by the Bureau of Standards the following facts have been demonstrated:

1. At least the majority of the coals from Franklin Co., Ill., and some from Pike Co., Ind., located in the mid-continent field, can be coked in byproduct coke ovens, and a fairly satisfactory grade of metallurgical coke can be produced. Likewise byproducts of reasonable quantity and good quality can be obtained from these coals.

2. The Roberts process at the time of these tests was still in the development stage, but credit should be given to Mr. Roberts for his work in connection with the coking of these coals. His efforts along these lines undoubtedly did much toward arousing interest among other coke-oven operators looking toward the use of mid-continent coals.

3. The bureau believes that at least some of the coal from the mid-continent field should be used in the coke-oven plants in the central section of the country. Even though the coke, on the whole, proved not to be uniformly as satisfactory as that from the so-called coking coals, the advantage due to the elimination from the coke-oven plants in the Eastern section will go far in overcoming any lack of quality of the coke. There can be no doubt that where domestic coke is wanted these coals can fulfill all requirements. Such uses will materially aid in the proper development of the fuel resources of the country.

Turret Furnace for Heat-Treating

A TURRET furnace with rotating hearth, to be used for the heat-treatment of iron and steel, has recently been installed at the plant of the Nash Motors Co., Kenosha, Wis., by the George J. Hagan Co., of Pittsburgh. Fig. 1 shows a view of the interior of the hearth. It may be noted that the stationary walls and arch are formed of specially shaped refractories, the clearance space between moving and stationary parts being closed underneath by means of a continuous sand seal. Fig. 2 shows an exterior view of the furnace, incased in sheet iron, properly reinforced. The rotating hearth itself is laid on a steel structure rotating on a series of twenty roller bearings. Six different speeds of rotation are available, from one complete rotation in thirty minutes to one in twenty-five minutes. Charging and discharging is done through adjacent doors, operated with compressed air. As shown in Fig. 1, a baffle wall extends across the heating chamber between the two doors to prevent the heated metal being chilled when charging cold material.

The first two-thirds of the furnace is maintained at a somewhat higher temperature than the remaining portion, this latter portion being a finishing or "soaking" zone.

All heating elements are separately connected to a General Electric control board, the temperature being

FIG. 1. INTERIOR OF THE HEARTH

automatically controlled by a two-point Leeds & Northrup potentiometer.

At night the current is switched off and the furnace loaded with iron or steel castings for annealing. In the morning the temperature will be about 1,000 deg. F., 40 minutes being required to reheat the furnace back to the working temperature—in the neighborhood of 1,525 deg. F. The furnace itself is 19 ft. outside diameter by 7 ft. high, while the diameter of rotating hearth is 15 ft., height 2 ft., and width 5 ft. It treats about 3,000 lb. per hour.

Some of the advantages claimed for this type of furnace are, first, a uniform rate of heat absorption, eliminating any distortion of long parts; second, an assurance that no metal will become overheated; third, practical elimination of scale, resulting in very much decreased time and acid consumption in pickling; fourth, the labor involved has been cut in half, from six to three men. The most important factor, however, is that the man in charge of the equipment may be supplied with a heat-treating ticket on which is shown the kind and number of pieces to be treated, the drawing temperature and speed of rotation of furnace hearth, and it is then an assured fact that these particular pieces will receive the particular treatment intended.

FIG. 2. EXTERIOR VIEW OF THE FURNACE

General Purpose Crawling Tractor Crane

THE Type BC "Industrial" crawling tractor crane, illustrated in the accompanying photograph, manufactured by the Industrial Works, Bay City, Mich., has been developed to meet the need for a full-revolving tractor crane which can be operated independently of rails. The crane is built in two types—the Type BC, with a capacity of 20,000 lb. at 12 ft. radius, is equipped with continuous crawling tractor belts; the Type BT, with a capacity of 18,000 lb. at 10 ft. radius, is equipped with four broad-gage tractor wheels.

The maximum utilization of yard storage space is realized with the use of these cranes, because their field of usefulness is not limited by railroad tracks, as in the case with the railroad crane. Having exceptionally

GENERAL PURPOSE CRAWLING TRACTOR CRANE

large capacities in ordinary lifting, they prove a valuable adjunct in those many erection jobs which are inaccessible to the railroad crane.

They can be equipped to handle a hook and block, grab bucket, drag scraper bucket, wood grapple, electric lifting magnet, shovel dipper and pile driver leads with drop hammer.

Operation is by means of an internal-combustion engine which has the advantages of being always ready for immediate use. When not in operation no fuel is consumed and it is not necessary, as often with a steam-operated machine, to have a licensed engineer as operator. Up to the capacity of the motor any combination of clewing, hoisting the load and varying the radius may be made.

The crane is equipped with a 30-ft. beam made up of two channels strongly latticed with angles and tie plates.

The steering of the crawling tractor crane while propelling is accurately controlled by the operator from his position in the revolving upper-works, by manipulation of the friction clutches and brakes controlling the motion of each tractor belt. By means of these clutches and brakes either tractor belt can be readily and instantly disconnected from the motor while the other belt continues traveling at the normal rate of speed.

The disconnected tractor belt can be held stationary by applying the brake, can be allowed to coast with the brake and clutch both disengaged, or the clutch can be allowed to slip, thus allowing operator to turn as sharp or as wide a corner as he may select. All the clutch-, brake- and lever-mechanism for steering is located in the revolving upper-works, where it is simpler and much more accessible than when a portion or all of this mechanism is located on the car-body.

Book Reviews

INDIA RUBBER GOODS MANUFACTURE. By "Factory Manager." London: Maclaren & Sons, Shoe Lane. Price \$7.75.

It is a pleasure to review the work of one who has honestly tried to set down his own experience and to describe in detail his best methods. This book is evidently the work of one who has actually been a factory manager. He knows how things are made. He is to be commended for producing such a detailed description of rubber goods manufacturing as he knew it. The work is quite voluminous, 484 pages, and discusses in more or less detail almost every phase of rubber goods manufacture.

However, it will be at once apparent to the American reader that it does not properly describe American practice. The reviewer is not familiar with English methods and cannot say as to how well they are covered. In so far as our methods are concerned the book covers those in vogue about five years ago. Except for druggists' sundries and mechanical goods the formulas given have been out of use for many years. Organic accelerators were unknown in the author's time. Black was used for coloring purposes only. Today most formulas of merit contain one or the other or both.

But do not let this worry the reader. The book contains many useful and valuable pointers in regard to the factory handling of various products. In a few lines the old methods are still followed.

Perhaps the only criticism in addition to being somewhat antiquated is that items of small importance, such as cash mats, are discussed to almost the same length as pneumatic tires, a subject of infinitely greater value.

From the mechanical goods and druggists' sundries standpoint the work is well done. Sizes and specifications are of course not applicable to American practice, but they give the reader an approximate idea of construction.

ANDREW H. KING.

Synopsis of Recent Chemical & Metallurgical Literature

Properties of Molybdenum Steels.—A paper giving tests on heat-treated Mo and Cr:Mo steels was presented by H. J. French before the recent meeting of the American Society for Steel Treating. The important features determined may be summarized as follows:

1. Steel containing 0.20 per cent carbon and 1 per cent molybdenum.

1. For each maximum temperature of heating there is a critical rate of cooling which will lower A_{r_1} . The higher the initial temperature the slower is the rate of cooling required to produce the lowered transformation, but by whatever combination this is produced the position of the "low point" is fixed within a narrow temperature range: about 525 deg. C. (975 deg. F.). Its suppression can readily be brought about, however, by increasing the rate of cooling.

2. A high temperature transformation is observed slightly above and almost merging with A_{r_1} when the steel is cooled from temperatures at or above 960 deg. C. (1,760 deg. F.) at a rate of temperature change approximating 0.15 deg. C. (0.27 deg. F.) per second, but is not observed when cooling at a much faster rate.

3. A_{r_2} is fixed at about 760 deg. C. (1,400 deg. F.) independent of the maximum temperature of heating or rate at which the steel is cooled.

4. The most suitable temperature from which to harden the steel is in the neighborhood of 910 deg. C. (1,670 deg. F.). Free ferrite is found after quenching from 830 deg. C. (1,525 deg. F.), but the observed changes in mechani-

cal properties with rise in quenching temperature within this range cannot be explained by known changes in carbon or iron, by differences in the rate at which the steel passes through the critical ranges resulting from changes in initial temperature of cooling, by unsatisfactory hardening or by the lowered A_{r1} transformation (except as related to a molybdenum change), for they are opposite to the changes found in plain carbon steel under similar conditions of treatment.

5. For the production of definite tensile strength, water-quenching is to be preferred on account of the higher proportional limit, ductility and impact values obtained, and conversely better tensile properties are obtained for a given impact resistance.

6. Raising the quenching temperature from 910 deg. C. (1,670 deg. F.) to 980 deg. C. (1,795 deg. F.) does not materially alter the mechanical properties of the steel when subsequently tempered at a relatively high temperature 540 deg. C. (1,000 deg. F.).

II. Steel containing 0.27 per cent carbon, 0.9 per cent chromium and 0.5 per cent molybdenum.

7. The A_{r1} transformation is first split and lowered when cooling from 960 to 1,000 deg. C. (1,760 to 1,830 deg. F.) at about 0.15 deg. C. (0.27 deg. F.) per second, the "low" point being observed at about 480 deg. C. (895 deg. F.). In water-quenching from the highest temperature, a lower hardness is obtained than when similarly cooling from 960 deg. C. (1,760 deg. F.). In this respect the chromium:molybdenum steel behaves similarly to steel containing 0.20 per cent carbon and 1 per cent molybdenum except that the observed changes are produced from higher temperatures.

8. In normalizing the chromium:molybdenum steel, a low limit of proportionality and impact resistance is obtained when using temperatures between about 780 to 845 deg. C. (1,450 to 1,550 deg. F.).

9. The fact that no material changes in tensile or impact properties are produced by oil-quenching the chromium:molybdenum steel from a wide range of temperatures when subsequently tempered at 540 deg. C. (1,000 deg. F.) has been confirmed. To produce high impact values in the hardened steel, a tempering temperature in the neighborhood of 650 deg. C. (1,200 deg. F.) is required.

Effects of Surface Scratches.—An important paper on this subject was read before the recent Engineering Conference of the British Institution of Civil Engineers by Prof. E. G. Coker. He noted that the importance of having a smooth surface in metals exposed to a high stress has been recognized by many engineers who impart a high degree of finish to their work, especially in cases where an intense stress varies cyclically, as in the moving parts of high-speed machinery. The increased strength and extension due to a high degree of polish in a tension test-piece has also been frequently noted, and the elimination of scratches appears to be of importance in many other cases.

It seems likely that the scratches produced by ordinary machining operations may be considered as minute notches in the surface, probably with plane or curved sides inclined at a considerable angle and rounded off at the bottom of the notch by curves with radii much greater than the average size of the unit of crystalline structure of the metal. If a scratch is made in the edge of a plate in tension, it may be shown¹ that a mean tension of one-third the yield point or even less will cause a permanent set at the scratch, while, if the load is alternating, these indentations gradually penetrate farther and farther into the material, apparently along planes inclined at 45 deg. to the line of pull in ductile bodies—that is, along the planes of maximum shear stress.

In a group of scratches sufficiently close to affect one another, the combined result is, naturally, still more noticeable, and the failure of a material under a comparatively moderate mean stress, due to surface scratches, is not difficult to understand, especially if the loading is of an alternating kind.

The form of the scratch is all-important. A scratch pro-

ducing a semi-circular groove in the material may raise the stress to about double the average stress, while a groove with straight sides at 45 deg. and a radius at the apex of one-eighth of the depth gives an increase of rather less than five times the mean stress. Increased sharpness of curvature at the bottom of the notch produces still greater local stress, and this latter may easily cause a fine crack to develop and produce failure owing to its rapid extension.

Surface of Liquid Steel.—Cosmo Johns read a short paper before the British Association, Sept. 13, 1921, on why liquid steel at 1,600 deg. C. was able to preserve its surface unoxidized. The author pointed out, as reported in *Iron and Coal Trades Review*, that this was especially noticeable in steel as it flowed from the furnace into the ladle. He had previously suggested that the obvious explanation was that the vapor of the steel formed a protecting medium, but there was some objection to this theory. He had noticed that sparks were given off the metal when it was being poured, and also that floating above the stream was a greenish fume. He found this to consist of minute spheres which on analysis proved to be all magnetic oxide of iron. It was not easy to get pure samples of this fume because of the impurities in the surrounding atmosphere, but he did succeed in getting some samples and made observations on a complex alloy containing other metals than iron. He found, as he had expected, that if the analysis of this oxidized material was calculated to the metallic elements from which it was formed, the result differed in no marked degree from the original steel as regards chemical composition.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Cellulose Ethers.—Alkyl ethers of cellulose, more particularly ethyl and methyl ethers, are prepared by treating cellulose or its near conversion products not soluble in alkali, such as mercerized cellulose, with a suitable alkylating agent in the presence of alkali, under such conditions that (1) the quantity of water present or added, disregarding water formed during the process, is at no stage of the etherification greater than about four times the weight of cellulose and preferably not in greater amount than about one-half and one-and-a-half times this weight, or it may even be as low as the natural humidity content of the cellulose, and (2) the total quantity of alkali is at least equal to and preferably exceeds by 3-19 or more times the weight of water present or added. The ethers so obtained are characterized by their insolubility in hot or cold water and by the fact that they are not precipitated from alcoholic solution by alcoholic solutions of alkali; and the same properties hold in the case of the intermediately formed partly etherified ethers. The requisite quantities of water and alkali are added prior to the alkylating process, or partly or entirely during the process, either continuously or by stages; and the alkylating agent is introduced all at once or continuously or in stages, but preferably in such a manner that an excess of alkali is always present. For making highly ethylated ethers it is necessary to employ relatively to one molecular equivalent of cellulose, $C_6H_{10}O_5$, 8-20 molecules of alkali and 5.9 molecules of diethyl sulphate. The temperature of the reaction varies according to the alkylating agent selected, etc.; in the case of diethyl sulphate, the temperature may be between room temperature or even lower, and 88 deg. C., but preferably below 55 deg. C.; with dimethyl sulphate, it is preferred to keep the temperature at 0 deg. C., or even lower; and in the case of alkyl halides the temperature is preferably raised to some point between 50 and 80 deg. C.

¹E. G. Coker, "Photo-elastic Measurements of the Stress Distribution in Tension Members Used in the Testing of Materials," *Min. Proc. Inst., C. E.*, 1921.

The reaction is accelerated by the addition of contact substances such as powdered copper or copper salts or hydroxides. It is advantageous to carry out in the reaction in the presence of liquid diluents such as benzene, which do not themselves suffer etherification, since such addition facilitates mixing and renders the reaction more uniform. In examples, one molecular equivalent of cellulose, etc., is kneaded with four molecules of caustic soda and an equal weight of water, and 1-2 molecules of diethyl sulphate are added while maintaining the temperature at 40-55 deg. C. or between ordinary temperature and 30 deg. C., with subsequent additions of 4-6 molecules of powdered caustic soda and 2-3 molecules of diethyl sulphate, and 4-6 molecules of caustic soda and 2-2½ molecules of diethyl sulphate, the products being eventually separated and washed with water; one molecular equivalent of cellulose, etc., is impregnated with an equal weight of water, kneaded with four molecules of caustic soda and 1½ molecules of diethyl sulphate added while keeping the mixture at a temperature of 40 deg. C., with subsequent additions at intervals of caustic soda and diethyl sulphate until a total of 12-18 molecules of the former and 6-8½ molecules of the latter have been added; one molecular equivalent of cellulose, etc., is impregnated with 20 per cent caustic soda and after standing is squeezed or centrifuged until the mass contains an amount of water equal to the weight of cellulose, whereupon 4½ molecules of caustic soda are added and the process continued as in the first example above; one molecular equivalent of cellulose, etc., is treated with a 50 per cent solution of 4 molecules of caustic soda, the mass thoroughly kneaded, then two molecules of dimethyl sulphate are added while maintaining the temperature at 5 to 10 deg. C., and subsequently 4-6 molecules of caustic soda and 2-3 molecules of dimethyl sulphate, and 4-8 molecules of caustic soda and 2-3½ molecules of dimethyl sulphate; and in these examples the diethyl and dimethyl sulphate may be introduced as a solution in an equal weight of benzene. By employing mixtures of different alkylating agents, "mixed" ethers may be obtained; or the cellulose may be partly etherified while employing one or more alkylating agents and then further etherified with another or others. The ethers obtained according to the above process may be employed in the manufacture of films, artificial filaments, celluloid-like masses, electric insulating materials, varnishes, dopes and coating materials. Aralkyl ethers, such as benzyl cellulose, and mixed ethers can be prepared in a similar manner. (Br. Pats. 164,374, 164,375 and 164,377. H. Dreyfus, London. July 27, 1921.)

Bornyl Esters; Borneol; Isoborneol.—Esters are prepared from turpentine and an acid, such as formic, acetic, butyric, sebacic, benzoic, salicylic, but preferably oxalic acid with the aid of a liquid "catalyst" such as methylene chloride, chloroform, carbon tetra-chloride, ethylene chloride or bromide, tetra-chlorethane or trichlorethylene; benzene and acetone are less effective. The "catalyst," turpentine, and anhydrous oxalic acid may be heated together at 115 to 125 deg. C., sufficient of the "catalyst" being used to bring the boiling point of the mixture to the required temperature. The product is mainly the neutral bornyl oxalate, from which excess of turpentine and the "catalyst" may be distilled first in vacuum and then in steam, and may be re-used. The ester is saponified by soda, and the solid alcohol oxidized to camphor by known methods. With sebacic acid, an acid ester is obtained. (Br. Pat. 164,357; not yet accepted. L. Darrasse and E. Darrasse of Paris and L. Dupont of Vincennes. July 27, 1921.)

Celluloid From Cellulose Ethers.—In the manufacture of solutions, films, artificial filaments, celluloid-like masses, electric insulating materials, varnishes, coating and other compositions, preparations and articles having as a basis the cellulose ethers described in specifications 164,374, 164,375 and 164,377, the alkylated sulphonamide derivatives or preparations described in specifications 132,283 133,353 and 154,334 are employed as high boiling point solvents or plastic-inducing agents; the cellulose ethers, esters used alone or mixed with other ethers, esters or derivatives of cellulose, and in conjunction with the sulphonamides there may be used other high boiling-point solvents such as triacetin, and lower boiling-point solvents or liquids, and other additions such as triphenyl or tricresyl phosphate, castor oil,

aliphatic derivatives of urea, coloring matters, filling materials, etc. In an example, a celluloid is prepared from an ether obtained according to the examples given in specification 164,374, using, as a high boiling-point solvent, benzene mono-methyl sulphonamide, toluene-o-monoethyl sulphonamide or mixtures of isomeric xylene mono-methyl or mono-ethyl sulphonamides, in conjunction with triphenyl or tricresyl phosphate, and alcohol or alcohol-benzene; the hardness of the product is adjusted by increasing and decreasing simultaneously the proportions of sulphonamide derivative and triphenyl or tricresyl phosphate. In another example describing a solution for use in the manufacture of films or as a varnish, the ether is dissolved in alcohol or alcohol-benzene, and the sulphonamide derivative added with or without triphenyl or tricresyl phosphate. (Br. Pat. 164,384, 164,385 and 164,386. H. Dreyfus, London. July 27, 1921.)

Forming Asphalt From Petroleum Residue.—The residue from the distillation of petroleum oils, distillates and tars is treated to form asphalt by heating it under pressure to 250-300 deg. C. and distributing it over inclined plates in a chamber heated to the same temperature, though which a current of air is passed. The apparatus is combined with

apparatus for distilling oils, etc., described in specification 163,363. (See CHEM. & MET. ENG., p. 669, 1921.) The oil, heated by passage through the tubes *P* in condensers *N* and through a tube *A* heated by an electric coil is distributed by funnels *H* onto inclined plates *E* in a chamber *D* also heated by a surrounding electric coil. The vapors evolved are withdrawn by a pump and condensed fractionally in a series of condensers *N*. The unevaporated residue passes to a vessel *L* and is pumped through a second heating tube *R*, and distributed over inclined plates in a heated chamber *S* to which air is admitted through a cock *U*. Vapors evolved in the chamber *S* are withdrawn through a series of condensers *X* cooled by passage of crude oil through pipes contained within them. In a modified apparatus, the heating tubes and evaporations are heated by gas or oil fuel burners, the residue from the first evaporator is passed through the cooling coils of the condensers connected to the asphalt chamber, and is passed through an intermediate heater and evaporator before being treated to form asphalt. (Br. Pat. 163,656. V. C. Illing and J. Kelly, both of London; July 13, 1921.)

Purifying Illuminating Gas.—A process for the purification of illuminating gas consists in first treating the gas in a washer with a liquid consisting of a solution of a ferrous salt and milk of lime and then with the solid residue filtered from the above-mentioned liquid after this residue has been exposed to the air and mixed with sawdust. In the first stage, the cyanogen in the gas forms prussiate of lime and remains in solution and part of the sulphuretted hydrogen forms iron sulphide which remains in the residue. In the second stage the residue when exposed to air forms a purifying material of ferric hydrate mixed with sulphur, sulphate of lime, carbonate of lime, etc., which removes the remainder of the sulphuretted hydrogen. (Br. Pat. 164,310; not yet accepted. Société du Gaz de Paris. July, 27, 1921.)

Current Events

in the Chemical and Metallurgical Industries

American Engineering Council

Unanimous election of M. E. Cooley, dean of the College of Engineering and Architecture of the University of Michigan, to be president of the American Engineering Council of the Federated American Engineering Societies was announced at a meeting of the executive board in Washington, Sept. 30. Dean Cooley's connection with the University of Michigan dates back to 1881; his influence on engineering practice in the United States therefore needs no emphasis. Among his many honors, the most recent was presidency of the American Society of Mechanical Engineers.

Resolutions were adopted expressing the opinion that the Lampert bill to remedy conditions in the Patent Office "provides the least increases in force and salaries which can possibly stop retrogression . . . and enable it to recover an efficient condition." Opposition was also voiced to the Stanley bill, a bill which requires that alien-owned patents must be worked in this country within two years else outsiders may obtain licenses to develop them.

In view of the unemployment among engineers, the need of a well-financed unified employment service and the inadequate contributions which the constituent societies can make toward such activities, a committee was appointed to work out a plan whereby interested organizations may co-operate in forming a "paid employment service, but in reduced fees to members of supporting organizations."

Government contracts were discussed at length, and the board made the following recommendations: "That Government work be normally carried out through unit price, or lump sum contracts, or by the purchase and hire method. Where none of the above methods are applicable to conditions, that the cost-plus method be used, in which the contractor is refunded the actual cost of the work, plus an accorded compensation which increases if the work is done below the estimated cost of the work and decreases if the work costs more than estimated, but never sinks below zero"; that an effort be made to standardize Government contracts and that partial payments be promptly made to contractors without the use of intermediaries.

In view of the business depression, it was decided not to hold an engineering assembly next January. The committee in charge of the arrangements was converted into a program and entertainment committee for the annual meeting of the council to be held in Washington in January.

The applications for membership of the Vermont Engineers Society and the Associated Engineers of Spokane were approved.

To Make Steel From British Columbia Magnetite

The Vancouver Magnetite Steel Smelting Co. has made arrangements to erect a 50-ton electric smelter at Nanaimo, on Vancouver Island, B. C., provided satisfactory arrangements can be made with the city. The city has appointed a committee to confer with Messrs. Fraser and Lewis of the company, and it is probable that a satisfactory understanding will be reached.

The company claims to have spent \$67,000 in experimental work and to have produced a high-grade steel from British Columbia magnetite. It will develop its own water power from the Nanaimo River; it claims to have \$5,000,000 of British capital behind it. The company is not purposing to use any new process, but those that have already been tried and proved in Norway and Sweden.

Increased Production of Alsatian Potash

It is reported that the Alsatian potash mines will double their output during October and that they will probably produced during 1922 10,000 tons of potassium chloride per month. Large quantities will be available for export.

Unemployment Decreases in Chemical Industry

An increase in the number of men employed in the chemical industry was shown during September, according to the figures of the U. S. Employment Service. The increase on Sept. 30 as compared with Aug. 31 was 2.6 per cent.

Chemical Tonnage on Railroads

Chemicals and explosives contributed 1,260,098 tons to the freight tonnage on class 1 railroads during the second quarter of 1921. Fertilizers to the extent of 1,800,407 tons were handled during the second quarter. The amount of vegetable oils moved was 262,808 tons. Pulpwood to the extent of 1,196,094 tons was shipped during that quarter. The figures are those of the Interstate Commerce Commission.

Metric System Bill Hearing

Hearings on Senator Ladd's metric system bill were to have begun Oct. 11. Among the witnesses who probably will appear in favor of the bill are Harvey W. Wiley, former chief of the Bureau of Chemistry; S. L. Hilton, president, American Pharmaceutical Association; Dr. Charles L. Parsons, secretary, American Chemical Society; William J. Schieffelin, a drug manufacturer of New York; Theodore H. Miller, works manager of the De Laval Separator Co., and Howard Richards, Jr., secretary, American Metric Association, of New York.

The executive board of American Engineering Council, which met in Washington Sept. 3, decided to take no part in the metric system controversy.

Iron and Steel Electrical Engineers Chicago Meeting

During the week of Sept. 19 the Association of Iron and Steel Electrical Engineers held its fifteenth annual convention at the Hotel La Salle, Chicago. Educational features included exhibits of representative manufacturers of electrical steel mill apparatus and inspection trips to plants in Chicago.

The fuel economy program was conducted under the auspices of the new section on Combustion Engineering. Fuel papers presented included "Fuel Requirements in Steel Mills," by S. E. Leahy; "Control of Boiler Operation," by W. S. Flannigan; "General Use of Oxygen in the Steel Mill Industry," by E. A. W. Jefferies, and "Waste Heat Utilization for Steam Generation," by G. R. McDermott.

The paper on "Fuel Requirements in Steel Mills" dealt with the various forms of fuels and touched upon the economic considerations such as transportation, storage and distribution, outlining some of the peculiar requirements and reasons why it is desirable to use various fuels in various steel mill operations. In the discussion on this paper attention was called to the desirability of taking occasional heat balances to assist in planning improvements and in properly proportioning the blast-furnace gases between the different services. Coke breeze is being used in increasing amounts in smaller plants, with an efficiency of 60 to 65 per cent. In especially designed waste heat boiler 27 tubes wide and 24 tubes high, efficiencies as high as 80 per cent have been secured as compared with the usual 70 per cent. Coke-oven gas has been burned with good results in open-hearth furnaces, but greater capacities are obtainable with tar.

In Mr. Jefferies' paper, on the "Influence of Cheap Oxygen on Economy of Fuel and Time," it was shown that the problem of cheap oxygen has been solved. When made at the rate of 4,000 cu.ft. per minute it can be produced for 8c.

per 1,000 cu.ft., as compared to the present rate of \$10 to \$15 per 1,000 cu.ft. when bought in the usual storage cylinder. In general, the process consists of liquefying the air by compressing and subsequent expansion to distill off the nitrogen in the liquid air columns.

In the steel industry and in other fields, the availability of cheap oxygen constitutes prospects of the greatest conceivable importance. The author intimated that fuel gas of 400 B.t.u. could be produced for 8c. per 1,000 cu.ft. The gas contained about 60 per cent carbon monoxide, which has a higher flame temperature than any other gas in general use, making it more desirable than coke-oven or natural gas.

Uses of oxygen in the open-hearth furnace, in the blast furnace and many miscellaneous places such as cutting metal welding and stimulating combustion were briefly touched upon by the author. The discussion centered upon combustion temperatures that would prevail when enriching in oxygen and the impossibility of present refractories withstanding such temperatures. If used in a power plant, it would necessitate the redesign of boilers and furnaces.

G. R. McDermott reviewed what has been accomplished in the utilization of waste gases for steam generation and pointed out sources of waste heat which may be available, referring in particular to open-hearth furnaces, soaking dips, reheating furnaces, malleable melting furnaces, forge furnaces and gas engines using blast-furnace gas.

To utilize the source of waste heat from blast-furnace gas the author has designed a high-mass velocity, fire-tube single-pass waste heat boiler to take the exhaust at a temperature of 850 deg. F. from 3,300-kw. gas-engine units. Based on an average load of 3,000 kw., it was estimated that the boiler would generate 2.6 lb. net of steam per kw.-hr. at the switchboard. Heat and absorption phenomena in direct-fired and waste-heat boilers were compared and the relative merits of water-tube and fire-tube boilers as absorbers of waste heat, the author favoring the last-mentioned type.

The officers elected for the coming year were: President, W. S. Hall, electrical engineer, the Illinois Steel Co.; first vice-president, R. B. Gerhardt, electrical engineer, the Bethlehem Steel Co.; second vice-president, L. F. Gailbraith, electrical engineer, the West Penn Steel Co.; treasurer, James Parrington, electrical superintendent, LaBelle Iron Works; secretary, J. F. Kelly, Pittsburgh, Pa.

The headquarters of the association are 1007 Empire Building, Pittsburgh, Pa.

Stainless Iron

According to the *Ironmonger* (London), a new stainless steel has been put on the market by three British firms in bars and sheets. It is derived from the well-known stainless steel, and differs from the latter principally in that it contains carbon less than 0.10 per cent. Carbon-free chromium or ferrochromium is thus required, either of which are expensive substances. Therefore the new metal is more expensive than brass, but it is easier to keep clean. This new low carbon chromium-iron alloy is distinctly softer than stainless steel and is thus suited to various manipulations: a wide range of uses in forging, pressing and stamping. Already success is reported in producing automobile wheel disks, hoods, bodies and other products subject to corrosion or tarnishing, thus eliminating painting and varnishing.

Reduced Duty for Earthenware Embossed in Mold

The Board of United States General Appraisers, New York, has handed down a ruling sustaining a number of protests against the assessment of duty at 40 per cent on imported earthenware embossed in the mold. The assessment at such rate under the provisions of paragraph 79 of the act of 1913 covers "decorated earthenware." The importers' claim, sustained by the board, covers an assessment of 35 per cent under the same paragraph, for "earthenware, not decorated."

Lecture Course in Burning of Clay Products

A course of twenty-five lectures on the burning of clay wares, firing of boilers in the pottery, firing efficiency and other phases of fuel combustion is being arranged at the School of Industrial Arts, Trenton, N. J.

Central Steel Co. Merger

Steel mill properties with combined assets in excess of \$20,000,000 have been brought together in the merger just completed of the Central Steel Co., the National Pressed Steel Co. and the Massillon Rolling Mill Co., all of Massillon, Ohio.

The new corporation, it is announced, takes the name of the Central Steel Co. and the following officers have been elected: Chairman of the board of directors and president, R. E. Bebb; first vice-president, F. J. Griffiths; second vice-president, C. C. Chase; third vice-president, H. M. Naugle; secretary and treasurer, C. E. Stuart.

The merger of the three companies brings the Central Steel Co. into prominent position among the largest steel producing corporations of the country, with complete modern equipment and facilities for producing all kinds of commercial alloy steels, hot- and cold-rolled sheets, hot-rolled strip steel and light structural steel sections in a combined annual output of 450,000 to 475,000 tons of finished material.

The Central Steel Co. brought to the merger ten open-hearth furnaces of 65 to 75 tons capacity, 34-in. blooming mill, 24-in., 18-in. and 12-in. finishing mills, 24-in. sheet bar mill, cold-drawing and heat-treating departments and a record of being the largest producer of strictly alloy steels in United States. The Central company annual tonnage runs from 300,000 to 325,000 tons.

The National Pressed Steel Co., which will function in the future as a division of the Central Steel Co., is a producer of hot-rolled strips and plates and finished structural steel joist sections with a present capacity of approximately 100,000 tons annually. Equipment is all modern and includes slab furnaces, annealing furnaces, complete pickling and finishing facilities, electro-driven hot-rolling mill with gage range from No. 15 to 1 in., widths up to 24 in. and lengths up to 130 ft., cold-forming steel lumber section mills, electric welders and other equipment for furnishing steel lumber finished and painted ready for use.

The Massillon Rolling Mill Co., which also will be operated as a division of the Central Steel Co., brings to the merger twelve hot sheet mills, sixteen cold sheet mills, eighteen annealing furnaces and complete equipment and facilities for turning out a complete line of sheet steel.

Declining Importance of Chilean Nitrate

Those charged with the operation of the Panama Canal see in the large decrease in nitrate shipments a factor having an important bearing on canal traffic. "The interests of the Panama Canal are affected," they state, "not only because nitrate made up one-third of the total northbound cargo in 1920, but because the smaller number of shipments has had an adverse effect on bulk cargo moving in the opposite direction. Vessels which carry coal cargoes south usually return with nitrates, so the decay of one involves a corresponding decline in the other."

The canal authorities attach importance to the following analysis of the nitrate situation by A. Bertrand, the delegate in Europe of the Association of Nitrate Producers:

"Before 1908, nitrate had but one rival, sulphate of ammonia, with a development very inferior to nitrate. From 1909 to 1913 cyanide and nitrate of calcium began to make their appearance, while at the same time the production of sulphate of ammonia increased much more than that of nitrate. In 1913, in its turn, synthetic ammonia made its appearance, though in a small proportion. In that year nitrate was still dominant.

"In 1917 the development of nitrate reached its maximum capacity. Synthetic ammonia was produced to a maximum degree in Germany in 1918. Sulphate of ammonia, extracted from coal, seems to have reached its full development in Germany and the United Kingdom and especially in the United States, while it continues to increase in other countries, notably Australia and Japan. At the present moment, the production of chloride of ammonia and other new salts is being encouraged for the purpose of fertilization.

"To sum up, nitrate, which represented 56 per cent of the world's total fertilizer production in 1913 to 1917, has fallen today to less than 35 per cent, according to the most favorable calculations, and it seems threatened with a descent to still lower depths in the current year."

Rubber Manufacturers' Association Organized

Rubber manufacturers at Trenton, N. J., have perfected plans for the organization of a new association, to be known as the Rubber Manufacturers' Association of New Jersey. The new organization is designed for mutual benefit of members, exchange of plans and ideas and for the general betterment of trade conditions. The trustees elected for the ensuing year include John S. Broughton, the United Globe & Rubber Co., president; Charles E. Stokes, an official of the Home Rubber Co., vice-president; A. Boyd Cornell, of the Hamilton Rubber Co., secretary, and W. H. Sayen, Jr., connected with the Mercer Rubber Co., treasurer. Offices will be located in the Broad Street Bank Building, with V. B. Wicoff as representative.

Personal

Dr. ELMER D. BALL has been chosen by the Secretary of Agriculture to be the first director of scientific work. The office was created in the last agricultural appropriation bill so as to provide an official who would be in immediate general charge of all research work in the department. Through Dr. Ball an effort will be made to co-ordinate and correlate the scientific work of the department in a way to make it more effective in the study of national problems having a bearing on agriculture.

M. J. CAVALIER, professor of metallurgy in the University of Toulouse, France, was the guest of honor at a meeting of the New York Section, American Institute of Mining and Metallurgical Engineers, on Oct. 5. Responding to a toast, he spoke on the influence of French universities on industries, and of the great expansion of the French metallurgical and electrochemical industry since the beginning of the war. As exchange professor, Dr. Cavalier will divide his time among Columbia, Harvard, Yale, Cornell, Johns Hopkins, Massachusetts Institute of Technology and the University of Pennsylvania.

J. D. CLARKE, general counsel for the Midwest Refining Co., Denver, Col., has been elected vice-president of the company to succeed R. D. Brooks, resigned.

MORTIMER ELWYN COOLEY, dean of the College of Engineering and Architecture of the University of Michigan, has been elected president of the American Engineering Council of the Federated American Engineering Societies. Dean Cooley assumes office at once and will carry out an extensive program in the interest of the public and the profession of engineering.

A. L. HALVORSEN of Perth Amboy, N. J., is planning to spend October and November in Germany and Norway inspecting the various activities in industrial chemical research and cyanide hydrometallurgy.

MILTON R. LOURIA, who completed his chemical engineering course at Columbia University last June, has been appointed instructor in chemistry at the University of Maine for the current year.

P. L. PALMERTON has been named chief of the newly established rubber division of the Bureau of Foreign and Domestic Commerce.

LINCOLN T. WORK has been appointed instructor in chemical engineering at Columbia University for the year beginning Oct. 1. Mr. Work completed three years of graduate work in the department of chemical engineering at Columbia last June.

Prof. ALFRED H. WHITE, director of the department of chemical engineering, University of Michigan, addressed the Rotary Club at Bay City, Sept. 20, on "The Chemistry of War."

Friends of Dr. HENRY M. HOWE will be sorry to know that for several weeks he has been practically confined to his bed with rheumatism.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Oct. 10, 1921.

Business in the heavy chemical market during the past week has been steadily improving and inquiries for a variety of minor commodities have been more plentiful. The general tone of the market was much stronger than during the past few weeks owing to the scarcity of spot material in resale quarters. Although buyers are still operating in a conservative manner, the volume of business has increased as the demand for finished products becomes greater. The general feeling in the trade is that a gradual revival will feature the market for the rest of the year.

The feature of the week's trading was the pronounced strength of prussiate of soda, cyanide of soda and soda ash. The market on these products closed very firm, with sellers showing very little desire to sell at the existing low prices. There has been an increased inquiry for solid caustic soda and the market is responding to increased buying orders. The demand for this material has been chiefly from domestic consumers. Soda ash is another chemical that has displayed considerable strength during the past few days. Glass factories are the foremost in the field of domestic consumers for this chemical and an increased inquiry has also been evidenced from smaller buyers. Bichromate of soda was reported a shade easier by some resale merchants in the final trading, while leading factors maintained their former price range.

CHEMICALS

Sellers of *bichromate of potash* ask 11@11½c. per lb., with several sales reported at the inside figure. The movement in this chemical has been somewhat dormant of late with the few inquiries passing calling only for small lots. Spot material does not seem to be plentiful, but competition is keeping prices irregular. Spot *carbonate of potash* has moved very quietly during the week and the market closed nominal at 4½@4¾c. per lb. for the 80-85 per cent, calcined. Imported *chlorate of potash* is offered at 6¾@7¼c. per lb., according to the quantity and seller. There has been no change noticed in the domestic goods and first hands quote their former price of 12c. per lb., f.o.b. works. Some sales have been recorded on spot *caustic potash*, 88-92 per cent, at 5½c. per lb. Offerings of this material were not heavy, but buyers were not eager to keep in line with the advance and therefore the demand eased up considerably. Shipment prices from Germany ranged from 5@5½c. per lb., with goods afloat held at 5c. Small lot sales of *bichromate of soda* were reported on the spot market at slightly lower figures. Quiet conditions for this chemical are responsible for the shading among holders of resale goods. Additional lots of standard brands were reported in the market at 7½@7¾c. per lb. A sale of 10 long tons was recorded early in the week at 7½c. per lb. f.a.s., N. Y. The late advances in solid *caustic soda* are being well maintained on spot and the market closed in a very favorable condition. Inquiries for small lots from various consuming quarters were quite frequent during the entire week and sales have been reported at \$4.05@\$4.15 per 100 lb., according to seller and quantity. At the works 3¾c. per lb., basis 60 per cent, was quoted for contracts on carload quantities. Sales of German *cyanide of soda*, 125-128 per cent, were recorded at 25c. per lb., with an exceedingly small supply of spot material around the market. Conditions in this chemical seem to be exceptionally bright and holders are backward in offering any round lots at present levels. Leading factors in *nitrite of soda* reports sales at 6¾c. per lb. The prevailing quotation was 6¾@7c. per lb., depending upon seller and quantity. There has been very little change in the attitude of consumers and operations have been confined chiefly to small quantities. Domestic *bleaching powder* in large drums is quoted at 21c. per lb., f.o.b. works. Sales of imported material have been made at 2c. per lb.,

ex-dock duty paid, while shipments from abroad are quoted at \$1.90 per 100 lb. The general demand for bleach from the various consuming trades has remained very active with paper mills leading the buying. Light *soda ash*, in single bags, is holding steady with sales reported at \$2.10@\$2.15 per 100 lb., depending upon the quantity. Sales of barrels are reported by dealers at \$2.45@\$2.50 per 100 lb. The feeling around the trade continues quite firm and a fair amount of business is passing at the above figures. Sales of small lots of *carbon tetrachloride* are reported at 11c. per lb. Larger quantities can be purchased below this figure, the price depending upon the quantity of the order. Prices on *muriate of potash* are slightly easier at \$38@\$40 per ton. Prices on spot *nitrate of soda* are somewhat firmer at \$2.25@\$2.30 per 100 lb.

COAL-TAR PRODUCTS

Conditions in the coal-tar products industry seem to be much brighter than at any time this year. There are still a few products where surplus stocks remain large and an undertone of weakness is noted on these, but on most of the other items there seems to be a healthier situation and holders show very little desire to loosen stocks at figures regardless of value. Manufacturers are operating in a more conservative manner, limiting their output to the actual requirements of the trade so that no stocks will accumulate. Buyers are showing more interest and are purchasing in larger quantities. Stocks of *naphthalene* are still heavy and holders are making concessions to realize some cash on their old stocks. The demand is very light, with prime white flakes offered at 6½c. per lb. Producers' prices remain unchanged at former levels. Resale *benzene* is still very difficult to locate and where small lots can be obtained a premium must be paid. Odd lots in drums have sold at 40c. per gal. for the c.p. grade. Refiners quote 28@33c. per gal., but cannot make any deliveries for some time. Supplies of *aniline oil* are still plentiful, but production has been greatly curtailed and any pronounced buying will undoubtedly strengthen the market considerably. Sales at 17½@18c. per lb. were recorded, according to quantity and seller. Odd lot sales of *beta-naphthol* were reported at 31c. per lb., but the general asking price around the market is 32c. First hands quote up to 40c. per lb., but are willing to shade this figure on actual business. Supplies seem to be quite abundant. Makers of *salicylic acid* quote the technical grade at 18@20c. per lb. The U.S.P. is being sold by second hands at 19c. per lb. The low prices quoted by first hands on *diethylaniline* has stimulated business to some extent and inquiries were more noticeable than any time during the year. Sales were made at \$1@\$1.10 per lb., depending upon the quantity. Low priced *dimethylaniline* has been cleared off the market and the best offering now heard is 42c. per lb. Manufacturers continue to ask 45c. and upward, but are not placing any actual round lot business at these figures.

WAXES

The demand for the lower grades of *beeswax* was reported much brighter, with the market, steady in all directions. African crude on spot was held at 15@16c. per lb. with shipment goods quoted at 13½@14c. per lb. Brazilian crude closed unchanged at 22@24c. per lb. Pure refined wax on spot held at 36@40c. per lb. Offerings of *candelilla wax* were noted at prices ranging from 24@25c. per lb., depending upon the quantity and seller. The demand was slow and the market barely steady. The call for *carnauba wax* was irregular and an easier feeling prevailed in various directions. Prices, at any rate, showed no important change, with the No. 2 North Country at 24@25c. per lb. and No. 3 North Country at 14½@15c. per lb. Small lots of *Japan wax* on spot brought as high as 26c. per lb. Offerings around the trade were light and sellers' views were quite firm, due to the recent advance in the cost of import. For round lots, the market closed at 24@25c. per lb. The demand for *paraffine wax* has once more fallen off so that refiners appeared quite anxious to meet the views of prospective buyers. Prices varied very little. The adverse exchange restricts any export business, while domestic consumers showed little disposition to buy in any quantity.

The Chicago Market

CHICAGO, Oct. 7, 1921.

Business in the general line of industrial chemicals continues very good and dealers appear well satisfied. While no really large transactions were reported, a very good volume of small orders was noticeable. There were practically no price changes reported and but little evidence of any shading of the present list.

INDUSTRIAL CHEMICALS

A firm tone still ruled in the market for *caustic soda*, although business was quieter. Supplies among second hands are small and 4½c. for the solid 76 per cent and 4¾c. for the ground were the prevailing quotations. *Soda ash* is still very firm and supplies could not be located under \$2.60 per 100 lb. for material in cooperage. *Sal soda* seems to be moving quite well at \$1.65@\$1.70 per 100 lb., although no large orders were reported. *Sal ammoniac* is unchanged as to price and is not moving so well. Prime white material, 98-100 per cent, is available at 7½c. per lb. A fair movement of *carbon bisulphide* was noted in some quarters and supplies were available at 7@7½c. per lb. The *formaldehyde* market is rather featureless, with supplies plentiful at 12c. per lb. *Glycerine* is quiet and firm, the prevailing quotation being 14½c. per lb. for drums. *Litharge* is not so active and the price is unchanged at 7½c. per lb. A fair movement of *lead acetate* was noted and prices are firm at 13@13½c. per lb. for small or medium quantities. *Caustic potash* is firm and unchanged as to price. Small lots are available at 6½c. per lb. for the 88-92 per cent material. *Bichromates* are quiet and supplies are said to be light. The potash salt is available at 13@13½c. and the sodium at 9½c. per lb., single cask lots. *Potassium permanganate* is very quiet and but few sales are noted. The prevailing quotation for spot U.S.P. crystals was 24c. per lb. *Sodium bicarbonate* continues to move in a fair way and the price is unchanged at \$2.60 per 100 lb. The demand for *sodium hyposulphite* has fallen off somewhat, but quotations remain at \$4.05 per 100 lb. for the pea crystal. *Acetate of soda* is meeting with a fair request at 5½@6½c. per lb. *Sodium fluoride* continues active and the price is unchanged at 11@12c. per lb. *Zinc chloride* is moving well at 11½c. for the domestic and 9@9½c. for the imported.

The acids as a rule were quite firm and on some the inquiry was much improved. *Acetic acid* is very firm, with practically all of the second-hand material absorbed. The 28 per cent in barrels is quoted at \$2.65@\$2.75 per 100 lb. and the glacial at \$10.25@\$10.75. A good inquiry for *oxalic acid* is reported and the domestic material is available at 17c. per lb. It appears that about all of the foreign acid has been absorbed. *Sulphuric acid* is moving quite freely and is unchanged in price, makers quoting \$19@\$20 per ton in tank cars, f.o.b. works.

VEGETABLE OILS

Linseed oil is in a weak position, according to a prominent factor, who predicts lower prices in the near future. Several small sales were reported, but the inquiry was light. The boiled oil is quoted today at 81c. per gal. and the raw at 79c.

NAVAL STORES

The naval stores market appears to be quite firm and dealers are reporting a very good volume of business. *Turpentine* is moving in a very fair way at 79c. per gal. drum basis, material in cooperage 5c. higher. *Rosin* is firm and moving very well, the "G" grade being quoted at \$5.35 per 280 lb. in carlots.

The Iron and Steel Market

PITTSBURGH, Oct. 7, 1921.

Viewed as a whole, the steel market is probably improving somewhat in volume of demand, while prices on the whole are not declining and are barely stationary, showing rather a slight stiffening tendency. Nevertheless the situation is not as good as was to be expected for the first week in October.

Consideration of conditions in the different products that make up the steel market as a whole does not enable one to generalize as to the fundamental conditions obtaining in

industry and commerce, but is useful even if it shows a negative result. Easily sheets constitute the most finished steel line. The Steel Corporation's sheet department is this week operating at about 90 per cent, while the independents as a whole are probably averaging 75 per cent or more. This operation, however, is predicated upon the large volume of business booked recently, in anticipation of the price advance that has since been in effect. Tin plate comes next in point of production, with mills operating at between 60 and 70 per cent.

The wire mills are operating at rates from 50 to 65 per cent, but the production is largely seasonal in character, and there is probably some stocking by jobbers and retailers, since orders now being filled were placed before the recent advances in mill prices.

The pipe mills are operating at an average of between 40 and 50 per cent. The demand for standard steel pipe is described as fairly good, not very far from normal, but line pipe and oil country goods generally are in light request and on account of the season of the year there is little prospect of improvement.

Production of steel ingots is scarcely at more than 35 per cent of capacity. The average is held down by light operation of bar, shape, plate and rail mills. The lightness of rail production is easily understood. The railroads bought conservatively for this year and are not taking out all their deliveries, being short of funds. Dullness in plates and shapes is ascribable to there being little construction work involving these materials, though there is much building of garages and dwelling houses. The lightness of demand for bars is not so easily understood, when there is fair demand for pipe, sheets and wire. Buyers of finished steel have been quoted prices averaging not more than about 30 per cent above the average prices of 1913, making an index number of 130 comparing with the Bureau of Labor's index number of all commodities of 152 for August, against 148 for July, so that steel prices have been relatively low.

The recent advances in wire products and sheets involved a sales campaign in which mills were ready to book orders at the old prices, while buyers were convinced that prices were going to advance. The operations were quite successful in placing tonnage on mill books. For several weeks past a number of mills making bars, shapes and plates have been conducting similar campaigns, but the operation has not been signally successful. While buyers may have been willing in most cases to place contracts for the remainder of the year, subject to specification from time to time as needs arose, they evidently have not been in position to put much tonnage on books in actual shipping orders. While the tonnage desired has not accumulated, a mill here and there has been disposed to stiffen in prices nevertheless. All three products can still be bought at 1.60c., but there is more disposition to hold to 1.65c. for bars and 1.65c. or higher for plates and shapes. There are reports that sales have been made at 1.50c. or less, but these are probably incorrect in all cases.

SEMI-FINISHED STEEL

Quite generally the mills are now quoting \$32 on sheet bars, by the so-called "advance" from \$30. Sales had actually been made at less than \$30 and no transactions have definitely shown a price above \$30. Billets are altogether neglected, some mills not having even an asking price. Nominally they are about \$30, with \$32 for small billets.

PIG IRON

The local pig-iron market has been very quiet, but furnaces expect a little buying movement very shortly. This would probably bring in some idle furnaces, so that it is not certain prices would advance. We quote: Bessemer, \$20; basic, \$19.25@ \$20; foundry, \$21, f.o.b. valley furnaces, freight to Pittsburgh being \$1.96. At a recent conference between iron and steel producers and railroad officials the sought-for reductions in ore, coke and limestone rates were denied, the assigned reason being that a general reduction in freight rates may possibly occur early next year.

Connellsville coke shows a stiffer tone and quotations are higher, though advances are not well supported thus far by sales. We quote: Spot furnace, \$2.35@ \$2.50; contract furnace, \$2.50@ \$2.75; spot foundry, \$4.25@ \$4.75.

General Chemicals

Ethyl Acetate pure (acetic ether, 98% to 100%)..... lb.			.40 -	.42
Formaldehyde, 40 per cent..... lb.	.11½ -	.12	.12½ -	.13
Fusel oil, ref..... gal.			3.25 -	3.75
Fusel oil, crude..... gal.			1.50 -	1.75
Glauber's salt (see sodium sulphate).....				
Glycerine, C. P. drums extra..... lb.			.14½ -	.15
Iodine, resublimed..... lb.			3.50 -	3.60
Iron oxide, red..... lb.			.10 -	.20
Iron sulphate (copperas)..... ton	18.00 -	19.00	20.00 -	23.00
Lead acetate..... lb.			.10½ -	.12½
Lead arsenate, paste..... lb.	.09 -	.09½	.10 -	.11
Lead nitrate..... lb.			.15 -	.20
Litharge..... lb.	.07½ -	.08	.08½ -	.09
Lithium carbonate..... lb.			1.30 -	1.40
Magnesium carbonate, technical..... lb.	.08 -	.08½	.09 -	.10
Magnesium sulphate, U. S. P..... 100 lb.	2.50 -	2.75		
Magnesium sulphate, technical..... 100 lb.			1.10 -	1.75
Methanol, 95%..... gal.			.66 -	.68
Methanol, 97%..... gal.			.70 -	.72
Nickel Salt, double..... lb.			.12 -	.12½
Nickel salt, single..... lb.			.14 -	.14½
Phosgene (see carbonyl chloride).....				
Phosphorus, red..... lb.	.40 -	.41	.42 -	.45
Phosphorus, yellow..... lb.			.30 -	.35
Potassium bichromate..... lb.	.11 -	.11½	.11½ -	.12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar) . . . lb.	\$. . . \$. . .	\$0 25 1/2 \$0 28
Potassium bromide, granular . . . lb.		14 20
Potassium carbonate, U. S. P. . . . lb.	20 - 21	22 25
Potassium carbonate, 80-85% . . . lb.	.04 1/2 - .04 1/2	.05 06

Sulphur chloride, red . . . lb.	.05 - .05 1/2	.05 1/2 - .06 1/2
Sulphur, crude . . . ton	18 00 - 20 00	
Sulphur dioxide, liquid, cylinders ex a . . . lb.	.08 - .08 1/2	.09 - 10
Sulphur (sublimed), flour . . . 100 lb.		2 25 - 3 10
Sulphur, roll (brimstone) . . . 100 lb.		2 00 - 2 75
Tin bichloride, 50 per cent . . . lb.	.18 - .19	
Tin oxide . . . lb.		.38 - 40
Zinc carbonate, precipitate . . . lb.	.16 - .16 1/2	.17 - .17 1/2
Zinc chloride, gran . . . lb.	.09 1/2 - .09 1/2	.10 - 11
Zinc cyanide . . . lb.	.42 - .44	.45 - 47
Zinc dust . . . lb.	.11 1/2 - .11 1/2	.11 1/2 - 12 1/2
Zinc oxide, XX . . . lb.	.07 1/2 - .07 1/2	.08 - .09
Zinc sulphate . . . 100 lb.	3.00 - 3 25	3 30 - 3 50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude . . . lb.	\$1.15 - \$1.20
Alpha-naphthol, refined . . . lb.	1 30 - 1 35
Alpha-naphthylamine . . . lb.	30 - 35
Aniline oil, drums extra . . . lb.	17 1/2 - 20
Aniline salts . . . lb.	24 - 26
Anthracene, 80% in drums (100 lb.) . . . lb.	75 - 1 00
Benzaldehyde U.S.P. . . . lb.	1 00 - 1 25
Benzidine, base . . . lb.	1 00 - 1 10
Benzidine sulphate . . . lb.	75 - 85
Benzoic acid, U.S.P. . . . lb.	60 - 65
Benzoate of soda, U.S.P. . . . lb.	52 - 55
Benzene, pure, water-white, in drums (100 gal.) . gal.	27 - 32
Benzene, 90%, in drums (100 gal.) . . . gal.	25 - 28
Benzyl chloride, 95-97%, refined . . . lb.	25 - 27
Benzyl chloride, tech . . . lb.	20 - 23
Beta-naphthol benzoate . . . lb.	3 50 - 4 00
Beta-naphthol, sublimed . . . lb.	70 - 75
Beta-naphthol, tech . . . lb.	32 - 35
Beta-naphthylamine, sublimed . . . lb.	1 90 - 2 00
Cresol, U. S. P., in drums (100 lb.) . . . lb.	16 - 17
Ortho-cresol, in drums (100 lb.) . . . lb.	25 - 27
Cresylic acid, 97-99%, straw color, in drums . . . gal.	70 - 75
Cresylic acid, 75-97%, dark, in drums . . . gal.	60 - 65
Cresylic acid, 50%, first quality, drums . . . gal.	45 - 50
Dichlorobenzene . . . lb.	.06 - .09
Diethylaniline . . . lb.	1 00 - 1 15
Dimethylaniline . . . lb.	.42 - .50
Dinitrobenzene . . . lb.	.25 - .28
Dinitrochlorobenzene . . . lb.	.25 - .30
Dinitronaphthalene . . . lb.	.32 - .40
Dinitrophenol . . . lb.	.37 - .40
Dinitrotoluene . . . lb.	.25 - .30
Dip oil, 25%, car lots, in drums . . . gal.	30 - 35
Diphenylamine . . . lb.	.60 - .70
Fluoride . . . lb.	1 10 - 1 20
Meta-phenylenediamine . . . lb.	1 15 - 1 20
Monochlorobenzene . . . lb.	.12 - .14
Monoethylaniline . . . lb.	1 50 - 1 60
Naphthalene crushed, in obls . . . lb.	.05 1/2 - .07 1/2
Naphthalene, flake . . . lb.	.06 1/2 - .08
Naphthalene, balls . . . lb.	.08 - .09 1/2
Naphthionic acid, crude . . . lb.	.70 - .75
Nitrobenzene . . . lb.	.12 - .15
Nitro-naphthalene . . . lb.	.30 - .35
Nitro-toluene . . . lb.	.15 - .17
Ortho-amidophenol . . . lb.	3 00 - 3 10
Ortho-dichlor-benzene . . . lb.	.15 - .20
Ortho-nitro-phenol . . . lb.	.75 - .80
Ortho-nitro-toluene . . . lb.	.15 - .20
Ortho-toluidine . . . lb.	.21 - .25
Para-amidophenol, base . . . lb.	1 40 - 1 45
Para-amidophenol, HCl . . . lb.	1 70 - 1 80
Para-dichlorobenzene . . . lb.	.15 - .20
Paranitroaniline . . . lb.	.79 - .82
Para-nitrotoluene . . . lb.	.80 - .85
Para-phenylenediamine . . . lb.	1 70 - 1 75
Para-toluidine . . . lb.	1 25 - 1 40
Phthalic anhydride . . . lb.	.40 - .50

Phenol, U. S. P., drums . . . lb.	.08 - .10
Pyridine . . . gal.	2 00 - 3 50
Resorcinol, technical . . . lb.	1 50 - 1 60
Resorcinol, pure . . . lb.	2 00 - 2 25
Salicylic acid, tech., in bbls . . . lb.	.18 - .20
Salicylic acid, U. S. P. . . . lb.	.19 - .22
Salol . . . lb.	.60 - .70
Solvent naphtha, water-white, in drums, 100 gal . gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal . gal.	.14 - .16
Sulphanilic acid, crude . . . lb.	.27 - .30
Tolidine . . . lb.	1 30 - 1 35
Toluidine, mixed . . . lb.	.43 - .45
Toluene, in tank cars . . . gal.	.25 - .28
Toluene, in drums . . . gal.	.28 - .31
Xylidines, drums, 100 gal . . . lb.	.40 - .45
Xylene, pure, in drums . . . gal.	.40 - .45
Xylene, pure, in tank cars . . . gal.	.45 - .45
Xylene, commercial, in drums, 100 gal . . . gal.	.33 - .35
Xylene, commercial, in tank cars . . . gal.	.30 - .35

Waxes

Prices based on original packages in large quantities:

Bayberry Wax . . . lb.	\$0 19 - \$0 20
Beeswax, refined, dark . . . lb.	.24 - .25
Beeswax, refined, light . . . lb.	.28 - .30
Beeswax, white pure . . . lb.	.36 - .42
Candelilla wax . . . lb.	.24 - .25
Carnauba, Florida . . . lb.	.48 - .50
Carnauba, No. 2, North Country . . . lb.	.24 - .25
Carnauba, No. 3, North Country . . . lb.	.14 1/2 - .15
Japan . . . lb.	.24 - .26
Montan, crude . . . lb.	.05 - .05 1/2
Paraffine waxes, crude match wax (white) 105-110 m.p. . . lb.	.03 1/2 - .03 1/2
Paraffine waxes, crude, scale 124-126 m.p. . . lb.	.02 - .03
Paraffine waxes, refined, 118-120 m.p. . . lb.	.03 - .03 1/2
Paraffine waxes, refined, 125 m.p. . . lb.	.03 1/2 - .03 1/2
Paraffine waxes, refined, 128-130 m.p. . . lb.	.03 1/2 - .04 1/2
Paraffine waxes, refined, 133-135 m.p. . . lb.	.04 1/2 - .05
Paraffine waxes, refined, 135-137 m.p. . . lb.	.05 1/2 - .06
Stearic acid, single pressed . . . lb.	.09 1/2 - .10
Stearic acid, double pressed . . . lb.	.10 - .11
Stearic acid, triple pressed . . . lb.	.11 - .11 1/2

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl . . . 280 lb.	\$5 55 - \$5 65
Rosin E-I . . . 280 lb.	5 75 - 6 25
Rosin K-N . . . 280 lb.	6 35 - 6 75
Rosin W. G.-W. W . . . 280 lb.	6 90 - 7 40
Wood rosin, bbl . . . 280 lb.	6 25 - .
Spirits of turpentine . . . gal.	.75 1/2 - .
Wood turpentine, steam dist . . . gal.	.73 - .
Wood turpentine, dest. dist . . . gal.	.72 - .
Pine tar pitch, bbl . . . 200 lb.	. - 6 50
Tar, kiln burned, bbl. (500 lb.) . . . bbl.	. - 11 00
Retort tar, bbl . . . 500 lb.	. - 11 00
Rosin oil, first run . . . gal.	.35 - .
Rosin oil, second run . . . gal.	.37 - .
Rosin oil, third run . . . gal.	.44 - .
Pine oil, steam dist., sp.gr. 0.930-0.940 . . . gal.	. - \$1.90
Pine oil, pure, dest. dist . . . gal.	. - 1 50
Pine tar oil, ref., sp.gr. 1.025-1.035 . . . gal.	. - .46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla. . . gal.	. - .35
Pine tar oil, double ref., sp.gr. 0.965-0.990 . . . gal.	. - .75
Pine tar, ref., thin, sp.gr. 1.080-1.060 . . . gal.	. - .35
Turpentine, crude, sp. gr. 0.900-0.970 . . . gal.	. - 1 25
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990 . . . gal.	. - .35
Pinewood creosote, ref . . . gal.	. - .52

Solvents

73-76 deg., steel bbls. (85 lb.) . . . gal.	\$0.37
70-72 deg., steel bbls. (85 lb.) . . . gal.	.35
68-70 deg., steel bbls. (85 lb.) . . . gal.	.34
V. M. and P. naphtha, steel bbls. (85 lb.) . . . gal.	.23

Fertilizers

Ammonium sulphate, bulk and d. bags . . . 100 lb.	\$2 15 - 2 50
Blood, dried, f.o.b., N. Y . . . unit	4 00
Bone, 3 and 50, ground, raw . . . ton	30 00 - 32 00
Cyanamide, f.o.b. works . . . unit	4 50
Fish scrap, dom., dried, f.o.b. works . . . unit	2 90 - 3 00
Nitrate soda . . . 100 lb.	2 25 - 2 30
Tankage, high grade, f.o.b. Chicago . . . unit	3 00 - 3 10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c . . ton	5 00 - 7 50
Tennessee, 78-80 p.c . . ton	8 00 - 9 00
Potassium muriate, 80 p.c . . ton	38 00 - 40 00
Potassium sulphate . . . unit	1 20 - 1 25

Crude Rubber

Para-Upriver line . . . lb.	\$0 21 - 21 1/2
Upriver coarse . . . lb.	.11 1/2 - .12
Upriver caucho ball . . . lb.	.11 1/2 - .12
Plantation—First latex crepe . . . lb.	.15 1/2 - .15 1/2
Ribbed smoked sheets . . . lb.	.15 1/2 - .15 1/2
Brown crepe, thin, clean . . . lb.	.15 - .15
Amber crepe No. 1 . . . lb.	.17 - .17

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls . . . lb.	\$0 10 - \$0 10 1/2
Castor oil, AA, in bbls . . . lb.	.11 - .11 1/2
China wood oil, in bbls. (f.o.b. Pac. coast) . . . lb.	.14 1/2 - .15
Cocoonut oil, Ceylon grade, in bbls . . . lb.	.09 1/2 - .10
Cocoonut oil, Cochin grade, in bbls . . . lb.	.10 1/2 - .10 1/2
Corn oil, crude, in bbls . . . lb.	.09 - .09 1/2
Cottonseed oil, crude (f. o. b. mill) . . . lb.	.07 1/2 - .08
Cottonseed oil, summer yellow . . . lb.	.09 1/2 - .10
Cottonseed oil, winter yellow . . . lb.	.10 1/2 - .10 1/2

Linseed oil, raw, ear lots (domestic)	gal.	67	—	.68
Linseed oil, raw, tank cars (domestic)	gal.	.62	—	.63
Linseed oil, in 5-bbl lots (domestic)	gal.	.70	—	.71
Olive oil, Denatured	gal.	\$1.10	—	\$1.20
Palm, Lagos	lb.	.07	—	.07 $\frac{1}{2}$
Palm, Niger	lb.	.06	—	.06 $\frac{1}{2}$
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08	—	.08 $\frac{1}{2}$
Peanut oil, refined, in bbls.	lb.	.11	—	.11 $\frac{1}{2}$
Rapeseed oil, refined in bbls.	gal.	90	—	91
Rapeseed oil, blown, in bbls.	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.08 $\frac{1}{2}$	—	—
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.07 $\frac{1}{2}$	—	—

FISH

Light pressed menhaden	gal.	\$0.40	—	—
Yellow bleached menhaden	gal.	.42	—	—
White bleached menhaden	gal.	.44	—	—
Blown menhaden	gal.	.48	—	—

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	20.00	—	24.00
Barytes, crude, 88% @ 94% ba., Kings Creek	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri	net ton	7.00	—	—
Blanc fixe, dry	lb.	.04	—	.04 $\frac{1}{2}$
Blanc fixe, pulp	net ton	45.00	—	55.00
Casein	lb.	.07	—	.10
Chalk, Precipitated, domestic, extra light	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, Precipitated, domestic, light	lb.	.04	—	.04 $\frac{1}{2}$
Chalk, Precipitated, domestic, heavy	lb.	.03 $\frac{1}{2}$	—	.04
Chalk, Precipitated, English, extra light	lb.	.04	—	.05
Chalk, Precipitated, English, light	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, Precipitated, English, dense	lb.	.04	—	.04 $\frac{1}{2}$
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points	net ton	13.00	—	20.00
China clay (kaolin), imported, lump	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.	net ton	18.00	—	—
Fullers earth, imported, powdered	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality	lb.	.06	—	.07
Graphite, Ceylon chip	lb.	.04 $\frac{1}{2}$	—	.05
Graphite, high grade amorphous crude	lb.	.00 $\frac{1}{2}$	—	.02 $\frac{1}{2}$
Kieselguhr, f.o.b. mines, Cal.	per ton	40.00	—	—
Kieselguhr, f.o.b. N.Y.	per ton	61.00	—	—
Magnesite, calcined	per ton	66.00	—	70.00
Pumice stone, imported	lb.	.03	—	.40
Pumice stone, domestic, lump	lb.	.05	—	.05 $\frac{1}{2}$
Pumice stone, domestic, ground	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore	net ton	—	—	10.00
Quartz (acid tower) 1 $\frac{1}{2}$ @2 in., f.o.b. Baltimore	net ton	—	—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore	net ton	—	—	17.00
Quartz, lump, f.o.b. North Carolina	net ton	5.00	—	7.50
Shellac, orange fine	lb.	.64	—	.65
Shellac, orange superfine	lb.	.66	—	.68
Shellac, A. C. garnet	lb.	.50	—	.52
Shellac, T. N.	lb.	.56	—	.57

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

PENTERS BLUFF—The American Manganese Co., 57 East Jackson Boulevard, Chicago, Ill., is reported to have plans under way for the erection of a new reduction plant in the vicinity of Penters Bluff, for the production of pulverized limestone. The plant is estimated to cost in excess of \$500,000. Manganese properties will also be operated in this district.

California

LONG BEACH—The California-Mexican Oil & Refining Co., Los Angeles, Vernon Dumas, head, is considering the construction of a new oil refinery in the vicinity of Long Beach, estimated to cost about \$450,000.

WILMINGTON—The Union Oil Co., Union Oil Bldg., Los Angeles, will break ground at once for the erection of its proposed new 3-story building at Wilmington, Los Angeles harbor. It will be 110 x 144 ft., and is estimated to cost \$250,000. A large laboratory for testing work will be installed. Ralph J. Reed is chief engineer.

Connecticut

WEST HAVEN—The West Haven Oil Co. has plans under way for the erection of new buildings at Elm and Water Sts., for general works service, to include tanks and other accessory equipment. Dwight E. Smith, Liberty Bldg., New Haven, is architect.

Illinois

CHICAGO—The National Rosin, Oil & Size Co., 3001-17 West Forty-seventh St., has filed plans for the extensions and improvements in its plant to cost about \$12,000.

CHICAGO—The Kaestner & Hecht Co., 500 Throop St., is taking bids for the erection of an addition to its foundry at Blackhawk and Cherry Sts., used for machinery and other metal casting production, to cost about \$30,000, including improvements in the present structure. Frank D. Chase, Inc., 645 Michigan Ave., is architect and engineer.

CHICAGO—The Oil & Chemical Corp., 4650 Iowa St., has acquired the entire block of property at Kirkpatrick Ave., Iowa and Walton Sts., totaling 248 x 504 ft. The company is now using a portion of the site and the remainder will be utilized for expansion. The property at one time was occupied by the Reedy Foundry Co. H. T. Dorington is secretary.

Kentucky

COVINGTON—The Michaels' Art Bronze Co., 230 Scott St., will commence the immediate erection of a 4-story and basement addition to its plant, 45 x 65 ft., to cost about \$40,000. F. I. Michaels is president.

Maryland

BALTIMORE—The Barclay Petroleum Co., 35 Wall St., New York, N. Y., is considering plans for the erection of a new oil refinery in the vicinity of Baltimore. The proposed plant will be equipped for operation under a centrifugal system of refining.

BALTIMORE—About \$100,000 will be expended by the Meadowbrook Dye Works, Inc., for machinery for installation at its proposed new plant on O'Donnell St., near Third St., comprising the former property of the Gunther Brewery. The building is 1-story, 96 x 140 ft., located on a site, 200 x 204 ft. The company was organized recently with a capital of \$200,000, and office at 523 Equitable Bldg.

BALTIMORE—The property of the National Vinegar Corp., St. Helena, near Baltimore, has been acquired by Emmet F. Sheridan and associates, who have taken possession. The property consists of a main 4-story building, 60 x 80 ft., with 2-story structure, 80 x 80 ft., and smaller

buildings. The new owners are forming a corporation to operate the plant for the manufacture of vinegar and byproducts. A number of improvements and extensions will be made, with the installation of machinery, estimated to cost about \$100,000. Plans have been filed for the immediate erection of a 2-story addition, to cost \$12,000. The former plant capacity will be doubled.

BALTIMORE—The Red "C" Oil Mfg. Co., Keyser Bldg., has had plans prepared for the erection of a new building at the Key Highway and Lawrence St., for general works service. W. H. Fehsenfeld is president.

Massachusetts

EASTHAMPTON—The Easthampton Foundry Co., Railroad St., has commenced the erection of a new 1-story foundry, 40 x 50 ft., with two wing extensions, 16 x 20 ft. The structure will cost about \$30,000. L. A. Moackel is president.

CHARLESTOWN—The Masury-Young Co., 198 Milk St., Boston, manufacturer of olive oil products, oil compounds, etc., has awarded a contract to the National Engineering Co., Boston, for the erection of a new 3-story plant on Roland St., Charlestown, 34 x 72 ft. A. D. Little, Inc., Cambridge, Mass., is engineer.

CHELSEA—The Revere Rubber Co. has had plans prepared for the erection of an addition to its plant to cost about \$20,000. Lockwood, Greene & Co., 245 State St., Boston, are architects.

Michigan

MANISTEE—Ruggles & Rademaker, 381 River St., have construction under way for a new salt manufacturing plant to cost in excess of \$500,000, with machinery. F. W. Perkins, company address, is architect.

New Jersey

CAMDEN—The Camden Pottery Co., Mt. Vernon and Orchard Sts., manufacturer of sanitary earthenware products, has construction under way on a new 2-story addition, 30 x 72 ft., at Orchard and Chestnut Sts., to cost about \$30,000. T. M. Dobbins is president.

New York

CORNING—The Corning Brick, Terra Cotta & Tile Co. has commenced the rebuilding of its plant, recently destroyed by fire with loss in excess of \$75,000. M. E. Gregory is president.

BUFFALO—The Dunlop Tire Corp., River Road, is planning to inaugurate operations at its new plant, recently completed, early in January, with a working force of about 2,500 men. The plant when entirely completed will represent an investment of close to \$20,000,000. P. D. Saylor is general manager.

BROOKLYN—Simon Garber & Sons, 1876 Pitkin Ave., manufacturer of oil products, have awarded a contract to the Turner Construction Co., 242 Madison Ave., New York, for the erection of a new 1-story building at Junius St. and Sutter Ave., to cost about \$200,000.

Ohio

NEWARK—The Leonard Oil Gas Co. is completing plans for the erection of a new oil refinery on East Street, estimated to cost about \$200,000 with machinery. The Rust Engineering Co., 1901 Fifth Ave., Pittsburgh, Pa., is engineer. J. W. Leonard is president.

CANTON—The Canton Oxygen Co., 1339 Yale Ave., N.W., manufacturer of commercial oxygen products, is having plans prepared for the erection of a new 1-story plant on Louisville Road, 47 x 90 ft. W. L. Stolzenbach is president. M. H. Miller, 319 McKinley Ave., S.W., is engineer.

Oklahoma

HENRYETTA—The Henryetta Glass & Mfg. Co. has awarded a contract for the erection of its proposed new local plant and construction will be commenced at once. A list of equipment to be installed

has been prepared, to include spraying machines, molds, mechanical fans and general manufacturing equipment. The new plant will specialize in the manufacture of chimneys, globes, shades, automobile lens and kindred products. The company was organized recently with a capital of \$50,000. H. L. Chambers is head.

Oregon

PORTLAND—The Columbia Tire Co., 1401 Northwest Bank Bldg., will soon call for bids for the erection of a new 2-story plant, 300 ft. wide, with four wings, extending to the rear, each 90 ft. long. It is estimated to cost about \$100,000. R. A. Wurzburg is head.

Pennsylvania

PHILADELPHIA—F. W. Tunnell & Co., 15 North Fifth St., manufacturer of fertilizer products, has awarded a contract to the Austin Co., Bulletin Bldg., for the erection of a new plant on Wheatshaf Lane, 1-story, 95 x 250 ft., estimated to cost about \$125,000. F. H. Tunnell is president.

EAST STROUDSBURG—The Nitroloid Co. has commenced operations at the former plant of the East Stroudsburg Glassware Co., recently acquired, for the manufacture of sheet celluloid and kindred products.

PHILADELPHIA—The United Chemical & Industrial Corp., Widener Bldg., has acquired a substantial interest in the Salts & Chemicals, Ltd., Kitchener, near Ottawa, Ont. The company will conduct certain operations, and plans to increase the capacity of the plant. Walter Whetstone is treasurer.

PITTSBURGH—The Air Reduction Co., 120 Broadway, New York, N. Y., manufacturer of commercial oxygen, etc., has filed plans for the first unit of its proposed new plant at 1100-16 Ridge Ave., to cost about \$60,000.

Tennessee

CHATTANOOGA—The Signal Mountain Portland Cement Co., James Bldg., will take bids during November for its proposed new local plant, estimated to cost in excess of \$500,000.

Texas

GROESBECK—The Magnolia Petroleum Co., Dallas, is planning for extensions in its plant at Groesbeck to cost in excess of \$500,000. A new pumping plant will be constructed and new tanks installed in the storage department of the works. E. A. Latimer is manager.

HOUSTON—The Ligol Chemical Co. has commenced the erection of a new plant on the Buffalo Bayou for the manufacture of liquid soaps, metal paint and affiliated products. It is proposed to commence operations at an early date. J. W. Crotty is president.

HOUSTON—The Sinclair Refining Co. is planning for the rebuilding of the portion of its plant on the Houston Ship Channel, recently destroyed by fire with loss estimated at about \$50,000.

Virginia

NORTH HOLSTON—The Southern Gypsum Co. is planning for the installation of crushing and other machinery at its plant. The company recently increased its capital to \$750,000 for expansion. Frank A. Wilder is president.

PULASKI—The General Chemical Co., 25 Broad St., New York, N. Y., will resume operations immediately at its local acid plant, placing two units in service, and giving employment to about 50 men. The plant has been shut down since March. It is expected to resume production in other departments at an early date.

West Virginia

PRINCETON—The Princeton Brick Co. is planning for extensions and improvements at its plant to double the present capacity. New machinery will be installed.

Washington

CHESTER—The Standard Stoneware Co. is completing plans for the erection of a new pottery for the manufacture of high-grade ware. It is proposed to break ground in October. Paul Seidel is president.

Wisconsin

MILWAUKEE—The J. Greenebaum Tanning Co., North Milwaukee, will take bids at once for the erection of a new 2-story tannery addition, 45 x 70 ft., estimated to cost about \$30,000.

Capital Increases, Etc.

THE KINGSTON PAPER Co., Little Falls, N. Y., has filed notice of change of name to the Niagara Felt & Paper Co. The latter organization has commenced the erection of a new plant on Sugar St., Niagara Falls, N. Y., to cost about \$300,000.

THE CARTHAGE BOARD & PAPER Co., Carthage, Ind., has filed notice of change of name to the American Paper Products Co.

THE PARAMOUNT RUBBER PRODUCTION Co. of New York, Waterloo, N. Y., has filed notice of dissolution under state laws.

THE HARRIS SOAP Co., 18 Stetson St., Buffalo, N. Y., has filed notice of increase in capital from \$35,000, to \$100,000.

THE PRINCE'S METALLIC PAINT Co., Allentown, Pa., has been adjudged an involuntary bankrupt.

THE MARYLAND VEGETABLE OIL Co., Fifteenth St. and Sixth Ave., Canton, Baltimore, Md., has arranged for a stock issue of \$2,250,000. John F. Nissly is president.

THE BARAHONA SUGAR Co., 129 Front St., New York, N. Y., has filed notice of increase in capital from \$16,000,000 to \$18,300,000.

THE BOONE OIL Co., 11 Broadway, New York, N. Y., has filed notice of increase in capital from \$7,000,000 to \$13,000,000.

A petition in bankruptcy has been filed against the BEVEL GLASS Co., 24 Downing St., New York, N. Y., manufacturer of mirrors, etc.

THE CARTHAGE SULPHITE PULP & PAPER Co., Carthage, N. Y., has arranged for a bond issue of \$600,000, for general operations, improvements, etc.

THE ALUMINUM Co. OF AMERICA, Oliver Bldg., Pittsburgh, Pa., has arranged for a bond issue of \$18,000,000, for general operations, financing, etc.

New Companies

THE DETROIT UNIVERSAL SOLVENT Co., Detroit, Mich., has been incorporated with a capital of \$25,000, to manufacture chemicals, paints, oils, etc. The incorporators are Wallace A. Armstrong, David S. Boyd and Harry W. Summers, 2691 Wreford Ave., Detroit.

THE AMIQUID Co., Boston, Mass., has been incorporated with a capital of \$500,000, to manufacture leather products. Frank A. Kamp is president, and Thomas M. Claffin, Brookline, Mass., treasurer.

THE PARK CHEMICAL Co., Brooklyn, N. Y., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts. The incorporators are J. A. and T. F. McGuinn, and J. Amico. The company is represented by E. J. Flanagan, 44 Court St., Brooklyn.

THE BENTON MFG. Co., 2130 West Van Buren St., Chicago, Ill., has been incorporated with a capital of \$5,000, to manufacture chemicals and chemical byproducts. The incorporators are Rupert Perböhner, Sidney Bisco and Solomon P. Roderick.

THE ALPHA PAPER PRODUCTS CORP., Brooklyn, N. Y., has been incorporated with a capital of \$5,000, to manufacture paper goods. The incorporators are W. G. Golden, M. Hoosack and F. D. McGarey, 51 Chambers St., New York.

THE ELECTRIC FOUNDRY & ENGINEERING Co., Wilmington, Del., has been incorporated with a capital of \$100,000, to manufacture steel and other metal castings. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE HERCULES SAPONA Co., INC., Boston, Mass., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. J. Sidney Stone is president; and Herbert P. Mason, Saugus, Mass., treasurer.

E. T. STILLE & Co., INC., 3422 Lincoln Ave., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture varnish, shellac, paint, etc. The incorporators are E. T. and D. E. Stille, and W. W. Bennett.

MCCOMB BROS., INC., Scarsdale, N. Y., has been incorporated with a capital of \$25,000 to manufacture chemicals and affiliated products. The incorporators are S. and J. B. McComb, and F. Winters, Scarsdale. The company is represented by Jacob Axelrad, 365 Broadway.

THE TENMESCAL OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$500,000, to manufacture petroleum products. The incorporators are L. K.

Adams, J. C. Gillham and C. C. Rich. The company is represented by Claud B. Andrews, 730 Merchants National Bank Bldg., Los Angeles.

THE BOULEVARD CHEMICAL Co., 381 Forest St., Jersey City, N. J., has filed notice of organization to manufacture chemicals and chemical byproducts. Robert H. Cohen, 42 Clendenny Ave., Jersey City, heads the company.

THE NASHVILLE PULP & PAPER Co., Nashville, Tenn., has been incorporated under Delaware laws with capital of \$1,250,000, to manufacture paper products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE JOHNSON HIGH TEST OIL Co., 503 State Bank Bldg., Freeport, Ill., has been incorporated with a capital of \$50,000, to manufacture petroleum products and byproducts. The incorporators are Harold W. Johnson, Edward J. Murray and Charles E. Johnson.

THE PERFEX PACKING FIBRE Box Co., New York, N. Y., has been incorporated with a capital of \$9,000, to manufacture fiber goods. The incorporators are L. Smith, Jr., B. I. Cantor and C. M. Hiesiger. The company is represented by Kleiner, Britwitz & Nadil, 399 Broadway.

THE SOLE WHITE LEATHER Co., Salem, Mass., has been incorporated with a capital of \$50,000, to manufacture leather products. Harold E. Hadley is president; and Thomas A. O'Keefe, 178 Lowell St., Peabody, Mass., treasurer.

THE NEW CORUNNA BRICK Co., Detroit, Mich., has been incorporated with a capital of \$25,000, to manufacture brick and other burned clay products. The incorporators are Henry F. Horn, Howard G. Harris and Christian P. Steinheiser, 1110 East Grand Boulevard, Detroit.

THE EL DORADO OIL REFINING Co., Tulsa, Okla., has been incorporated with a capital of \$500,000, to manufacture refined petroleum products. The incorporators are L. F. Severson, Tulsa; G. W. and L. F. Merrill, both of Texarkana, Tex.

THE ARKANSAS Co., New York, N. Y., has been incorporated with a capital of \$10,000, to manufacture oils, chemicals and kindred products. The incorporators are M. Braham E. F. Katzenhuber and A. A. Kelley. The company is represented by H. H. Neiman, 160 Broadway, New York.

THE KUEHN-CASWELL Co., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture insulating materials, compounds, etc. The incorporators are W. G. Kuehn, E. T. Caswell and J. E. Finegan, 5 Beckman St., New York.

THE UNITED STATES NON-METALLIC MINERALS CORP., Los Angeles, Cal., has been incorporated with a capital of \$100,000, to manufacture refined mineral products. The incorporators are C. H. Dickinson, S. H. Deyot and H. J. O'Brien, 801 Brent Ave., South Pasadena, Cal.

THE POTASH-MARL Co., INC., Marlton, N. J., has been incorporated with a capital of \$50,000, to manufacture potash products. The incorporators are Harry T. Martin, George F. Pentecost and Stanley Silliman, all of Marlton.

HUNNELL & Co., INC., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture oils, chemicals, etc. The incorporators are L. C. Hunnell, G. A. and G. W. Heath, 136 Liberty St., New York.

THE WESTERN GYPSUM PRODUCTS Co., Los Angeles, Cal., has filed notice of organization to manufacture gypsum specialties. M. E. Edwards, 3433 Hollenbeck St., Los Angeles, represents the company.

THE COLUMBUS FERTILIZER Co., Columbus, Ga., has been incorporated with a capital of \$15,000, to manufacture commercial fertilizer products. The incorporators are O. C. and Drane Bullock, and C. M. Neal, all of Columbus.

THE C. A. REED Co., Williamsport, Pa., has been incorporated with a capital of \$303,000, to manufacture paper products. Construction of a new plant will be placed under way at once, to be located at Laurel and Willow Sts., and estimated to cost approximately \$100,000. Harry A. Miller is treasurer.

THE KEMOZONE LABORATORIES, INC., Buffalo, N. Y., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are M. J. O., and O. F. Cabana, Buffalo. The company is represented by Norton Bros., Brishane Bldg.

THE W. R. HOLLINGSHEAD CHEMICAL Co., New York, N. Y., has been incorporated under Delaware laws with a capital of \$1,000,000, to manufacture washing com-

pounds and other chemical products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE R. & G. RUBBER Co., New York, N. Y., has been incorporated with a capital of \$5,000, to manufacture rubber products. The incorporators are S. Zimmerman, S. Klein and H. Booke. The company is represented by J. M. Wolf, 2 Rector St., New York.

THE NATIONAL GRAPHITE Co., Kittery, Me., has been incorporated with a capital of \$500,000, to manufacture graphite products. Dexter B. Pattison is president, and Horace Mitchell, treasurer, both of Kittery.

THE WESTMORELAND LIME PRODUCTS Co., Wilmington, Del., has been incorporated under state laws with capital of \$100,000, to manufacture lime and affiliated products. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington.

THE GLOBE FIBRE Co., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture fiber products. The incorporators are H. Silverman, K. Axelrod and Abraham Grometstein, 41 Park Row.

THE BANGOR PULP WOOD & LUMBER Co., Bangor, Me., has been incorporated with a capital of \$100,000, to manufacture pulp products. Arthur G. Anderson is president and treasurer, and Donald F. Snow, secretary, both of Bangor.

THE CARBONDALE MFG. Co., New York, N. Y., has been incorporated with a capital of \$200,000, to manufacture refined oil products. The incorporators are F. Schaerer, J. F. McDavitt and K. Drinane. The company is represented by Kaye, McDavitt & Scholer, 149 Broadway, New York.

THE STEAM BOILER MATERIAL Co., 718 West 63d St., Chicago, has been incorporated with a capital of \$15,000 to mine, manufacture and deal in products of fire clay, firebrick, furnace linings, etc. The incorporators are Charles A. Miller, Arthur T. Leafy and Charles Vlaricoates.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada. Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS will hold its thirty-eighth annual convention at the Washington Hotel, Washington, D. C., Oct. 24-26.

INDUSTRIAL COST ASSOCIATION will hold its second national conference at Pittsburgh, Pa., Nov. 2-4, with headquarters at the William Penn Hotel.

INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA will hold its annual convention at the Waldorf-Astoria, New York, Nov. 1-5.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 342 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

Coal, and the Rocky Road To Normalcy

STRIKES at hand and in prospect! Wars and rumors of wars! Peace that Senates will not ratify!

Such is our topsy-turvy world, a psychological maelstrom which keeps nations arming against they know not what, industries filling their stocks to withstand a state of siege, and the individual hoarding necessities against the hour of trouble. Such obstructions beset the return of sanity in us all.

The recent conference on unemployment emphasized how intimately the mental outlook affected everyday affairs. Almost everyone can see that slow trade and few jobs are cause and effect, and effect and cause; but we need to be reminded that the very realization of slow trade and a vision of jobless men intensifies that very condition. "Millions of people out of work! When will it hit me? Guess I'd better go slow!"

So narrow is the ledge which separates prosperity from panic and credit from ruin that it is crossed almost over night by a wave of thought. This doubtless is the reason why men who are really conversant with conditions throughout our country, and even of the world, are very careful against spreading alarming reports unless they are absolutely justified in doing so. And in this very direction lies a great fault in our Hallowe'en boggy, the threatened railroad strike. It is perhaps unreasonable to expect labor unions to give up their most efficient weapon, the strike, but it does seem hasty to brandish tomahawks and beat the tocsin now.

Doubtless many such considerations are the underlying reason why public officials and the press have had so little to say about the coal situation. Or it may be our national business policy not to borrow trouble; not to worry much about what can be foreseen—let it arrive and then make shift. But that is certainly not the way of engineers. In their work they must visualize all probable combinations of circumstances, and provide ways and means of preventing or handling them.

So, looking beyond the present railroad scare, they should be informed that there is unquestionably going to be trouble in the coal fields next spring. Operators have already agreed to arbitrate any question of wages, but the unions in recent convention at Indianapolis stand firm on a wage increase. Undoubtedly, this means no coal next spring, either bituminous or anthracite.

With this in view, managers would be well advised, and engineers would do well in emphasizing the fact, that several months' coal should be stored *now*. Deliveries are now prompt, and will be slow after New Year's. A drop in price sufficient to cover the risk of unpreparedness cannot be expected. Furthermore, generous purchases of coal would do much to relieve one most acute spot on the unemployment map—in the bituminous coal fields.

Do it now, and help over the bumps along the road to normalcy!

Internal Strain Versus Amorphous Metal

BEILBY'S theory of amorphous metal, as later extended by various scientists, has enjoyed such widespread acceptance among American metallurgists and has been put to such good uses that we sometimes forget the fact that a strong contingent of European workers declines to subscribe to the soundness of the idea. A leader of these "dissenters" is Professor E. HEYN. His comments on JEFFRIES and ARCHER'S recent publications on the hardening theory are printed on page 728 of this issue. In order that there may be readily available a statement of what Professor HEYN considers the greatest obstacle to the theory of amorphous metal, his "Theory of Strengthening of Metals by Cold-Work" has been translated and abstracted on page 735. Unfortunately, space limitation has made it necessary that this material be highly compressed. However, a great deal of pains has been taken to avoid distortion of the original meaning, and those who are using metallurgical theory will undoubtedly study HEYN'S ideas with interest.

In denying the amorphous theory, HEYN insists that a theory of latent tensions or of internal strain can be applied directly to a single-phase alloy, a metal wholly crystalline to the smallest particle. It is therefore surprising that he finds it necessary to visualize the mechanism of the imagined actions by the use of a compound substance composed of two such dissimilar materials as steel springs and modeling clay. However, this is a remark in passing and no sound reason for dismissing the theory.

And, without inferring that BAUSCHINGER'S published results have led to incorrect generalizations, it should be stated immediately that the development of optical methods for making a continuous record of a tension or compression test has given the investigator an implement of precision with which to make a searching survey of the field of elasticity. Without waiting for this critical examination it is agreed that when a metal has been loaded beyond its original limit of flow and then unloaded, it retains within it a certain amount of elastic strain and a corresponding stress which is held in equilibrium by some internal force similar to frictional resistance. In other words, when a test-bar is pulled, the crystals deform very slightly in shape and size, acting in an elastic manner up to the limit of flow, when their capacity for further homogeneous distortion is exhausted and further movement takes place by slip of crystalline blocks along their cleavage planes, partly relieving the load, permitting some of the crystalline fragments to return toward their original atomic spacing temporarily. However, the great majority of the crystals continue under distortion which approaches the breaking point.

One does not need to postulate amorphous layers around the crystalline blocks to grant that when the

external load is relieved, the distorted crystals visualized by HEYN as springs must exert a certain amount of pressure against their surroundings before the bar as a whole should contract. Crystal interlocking might be called upon to explain this lag. Entire relief of external loading, in other words, leaves the crystals in possession of a small residual deformation, corresponding to an internal strain similar to that imposed by external tension. By "internal" probably everyone (even Professor HEYN) means "within the test-piece" rather than "within the space lattice," for it is not admitted that physical distortion below the elastic limit can introduce something into the relations *between* atoms which would prevent recovery of normal spacing; strained crystals are due to forces acting somewhere upon their surfaces.

If it be assumed that the residual compressive strains are so arranged that they must be relieved on a second loading before the crystalline blocks take any additional deformation, no extension of the piece will be measured until the external load is sufficient to balance the internal resistance holding the internal stresses in equilibrium. But when that time comes, the crystalline blocks of our conception, or the springs of HEYN'S, are by no means free of stress, as Professor HEYN would have us suppose when he moves the origin of his stress-strain diagram and measures internal stresses from the new position. The elastic portion of the metal retains the residual deformation it possessed before reloading, and consequently the corresponding internal stress, a stress which is in the same sense as that imposed by the second loading in tension. Hence, considering only the distortions in the crystalline blocklets, it is difficult to see how the unit stress at their limit of flow will be in any way different or located on a different abscissa in the stress-strain diagram than on the first loading. Rather it is the compression loading on the surrounding material (likened by HEYN to frictional resistance) which is relieved by the first loads applied, and whose subsequent tension stresses may be measured from the transformed axis. However, Professor HEYN denies the actual existence of any such substance in a single phase metal, although he visualizes it as a thing so non-metallic as clay.

But only for the time being! In order to explain the lowered limit of flow in compression, it is apparently necessary to have the commanding part of the material free of stress at point *D* of his diagram (page 736). Therefore the "plastic mass" which held the "springs" in tension on relief of the first tension loading suddenly transforms itself into "springs" in compression, and this is the stuff which fails first in the subsequent compression test and so extensively as to produce flow at a low load. Howbeit this stuff is non-existent.

At any rate, if Professor HEYN'S views on residual stresses in overstrained metal be accepted, his hypothetical springs in tension be replaced by the actual crystalline blocklets, slightly deformed, and these ideas be then used to explain the higher flow limit on repeated loading and a lower flow limit in opposite loading, one is led to the conclusion that the material surrounding the crystalline fragments and holding them in position must have more influence in shaping the stress-strain curve than the blocklets themselves. This is true, whether we conceive this cementing material to be amorphous metal, or, with HEYN, merely layers of atoms pulled or pushed slightly out of their crystallographic positions and existing in a state of elastic strain.

Act! but

Think First

JUST because we brought out an important issue of this magazine in which we endeavored to point out where the faults lie in various chemical and metallurgical industries, we do not want to become common scolds. We want to take a cheerful view of life. But we think it worth while occasionally to look at the reverse side of some leading examples, and, without criticising the eminent men who have set them, to point out how such examples may be misused.

One of the most frequent references to the late ANDREW CARNEGIE is that he was never afraid to make a big scrap-heap if he had something better to take the place of what was discarded. The idea of that very canny and provident Scotchman, ruthlessly tearing down valuable equipment to throw it away, seems big and strong and mighty. If a thing is no good, get rid of it! Don't be afraid! It sounds fine. But unfortunately it has become the slogan of the wastrel and the man who is lazy in his mind. "Cut it out and call it a loss," we say; and then we smile at ourselves for our courage.

The other day we came across an Indiana farmer who is doing very well. He said when he took the farm over he was short of money to buy the machinery he needed, and among other things he lacked a corn planter. A neighbor had lately bought a new one and discarded his old one—which was laid out in the weather alongside of his new one. "What do you want for the old corn planter?" the young farmer asked. "It's no good," said the neighbor; "it's all used up. It's junk." "But what do you want for it?" he persisted. "I tell you it's all used up; you can have it for a dollar." So he bought it for a dollar, took it home, took it apart, oiled it and got the rust off, used it successfully for two years and then sold it for forty dollars when he needed a larger one.

Often we treat processes and whole industries just as the neighboring farmer did. They don't work and so, being ambitious to be drastic and powerful and resolute, we say: "Cut it out! Send it to the scrap-heap!" What we lack in our head-pieces is patience and persistence along with industry. We pride ourselves on thinking quickly when we don't think at all. We misuse CARNEGIE'S careful study and the superior technical information and advice with which he provided himself abundantly as a cover for our own ignorance and laziness.

These quick decisions to quit early or before a thing is determined by painstaking study and information, which are supposed to represent activity of mind and peculiar resolution but which in fact are nothing more than ignorance and bullying, are the despair of research. If a man speaks short and quick, that is no reason to believe that the activity of his mind is short and quick. He may not think at all. Very often he doesn't. He can dress his words as though he were a captain of dragoons while he uses his mind as though he ran a peanut stand.

The country is full of the corpses of enterprises that might have been going and producing concerns if it hadn't been for this loud-mouthed slap-dash impatience of ignorance. The destroyers are of the kind that declare they have no time for theories; that if you have anything that is all tried out and proved they will give it attention, but they prefer to let some other fellow do any experimenting that may be needed. And where should we all be today if nobody had ever had any use for theories or any willingness to experiment? We should be back in the woods, climbing trees!

Tinkering With Scientific Bureaus

OUR opinion has been requested regarding a scheme for the reorganization of the scientific bureaus of the Government and we cannot refrain from offering a few comments on the nature of that request. We received four closely typed pages across the first of which was written the touching appeal, "Will you please publish this in whole or in part?" while at the bottom of the last page and beneath the signature of our correspondent was the following postscript: "Please write soon to your Senator and Congressman urging this plan." The plan itself is simply this—all of the scientific bureaus of the Government are to be consolidated under one department. This idea, to be sure, is not entirely new, but in other respects the plan is not at all lacking in novelty. The suggestion of creating a new department of science is summarily dismissed, for "already there exists an institution which has great prestige and represents the science of the Government in a general way. It is the Smithsonian Institution." Just why the Institution was chosen is not exactly clear unless it is believed that bureaucratic life is now extinct and the bureaus themselves are ready for the museum!

Our would-be reformer, however, is really serious. He lists in all thirty-two scientific bureaus which, with their personnel and appropriations intact, should be transferred to the Smithsonian Institution. Among these we note the Patent Office, the Bureau of Fisheries, the Library of Congress, and even the Government Hospital for the Insane! Such is the rare combination to be effected in the interests of efficiency.

But we are told that there is appalling duplication in these scientific bureaus. For instance, the Library of the Smithsonian Institution contains 100,000 volumes, twice this many are in the Surgeon General's Office, and each of the other scientific bureaus maintains its own specialized library. Now all these libraries are to be combined under the Smithsonian Institution in order (to use the words of our correspondent) "to reduce expenses by avoiding duplication of books." Imagine the line forming on the right for consulting Vol. III of Thorpe or glancing through the pages of the latest number of CHEM. & MET.

And still there are many other reasons why this super-government control should be vested in Smithsonian. The consolidation "will tend to give more influence and efficiency to science and divorce it from the evils of politics." Furthermore, "many of the bureaus now have little influence and consequently *the scientific workers are paid shameful and minimum salaries.*" The italics are ours, for we feel that here we have struck the real keynote of the proposal. Our conviction is confirmed a little farther down in the brief, where we find the suggestion that "in inviting scientific men to take up *permanent* work with the Government, it is understood that they cannot be removed from their positions without very serious charge. . . . A true scientist in love with his work is more concerned with the permanency of his position and independence in his work than in the salary he obtains" and therefore "is always willing to make some sacrifice if necessary when the good of all Government science is at stake."

We have been asked for our opinion, and we are frank to admit that to us the scheme appears most ridiculous. It is the sort of propaganda that obscures the real issue and contributes nothing toward the solution of one of the most serious problems confronting the Government.

The Congressional Joint Committee on the Reorganization of the Administrative Branch of the Government needs practical, workable suggestions and scientific societies asked to indorse such schemes as this will do well to weigh their recommendations most carefully.

Iron Industry

As a Barometer

LONG ago it was said that "iron is the barometer of trade," but the barometric or prophetic character of iron demand is only partial. It obtains chiefly in connection with construction work. It is characteristic of much investment construction, the kind that looks to a long period of time for returns, a skyscraper office building being a particularly good illustration, that it is undertaken when costs are low—i.e., when general business is relatively inactive. As it requires a long time for the completion of such construction jobs and as periods of inactivity and activity alternate, the jobs undertaken when business is inactive are usually completed when business is active. Among the first contracts let is the contract for the steel, and the letting of the contract is prophetic that later workmen are going to be employed in erecting the buildings and putting on the finishing touches.

Of a totally different character, as to its connection with trade movements, is steel bought by railroads either directly or in the form of equipment. In the past the railroads have not bought much steel until business had improved and their traffic had increased. In the past one would have had to be quite blind to avoid seeing that business had improved until he observed that the railroads were making purchases on a liberal scale. The rule will apply to the immediate future. Until there is a very material increase in freight traffic the railroads will not buy freely.

In still another category is the steel that is bought directly or indirectly by the general public for current consumption, corrugated sheets, wire fence, agricultural implements, etc., by the farmer, tools by the mechanic, household wares by the housewife, and so on. This buying follows rather than precedes an improvement in business.

Some demand for steel precedes, some demand accompanies and some demand follows an improvement in general business. Only part of the steel demand is barometric or prophetic. If one wishes to obtain an indication for the future he should not take the demand for steel as a whole, but should scrutinize the steel market in detail and pick out the particular classes that are indicative along this line. The sales of Fords to farmers are one thing, the fabricated steel lettings, as reported by the Bridge Builders' and Structural Society, are an altogether different thing.

As to the divergence in conclusions reached by observation of the steel market in the recent past, that is due largely to the finished steel business having divided itself into two classes. One class includes sheets, wire products, tin plates and tubular goods. Demand for these has been and is relatively good. The other class includes bars, shapes, plates and rails. Demand for these has been and is very poor. Materials in the first class are widely distributed and the demand for them betokens a very fair degree of common everyday activity. Materials in the second class run more to construction work, investment buying and railroad buying. They make "the tonnage" in steel, and when they are in poor demand the steel output is low.

Readers' Views and Comments

The Slip Interference Theory of the Hardening of Metals

To the Editor of Chemical & Metallurgical Engineering

SIR:—I read with keen interest the important contribution by Dr. Zay Jeffries and R. S. Archer, which sheds light on many dark points, and I am glad to avail myself of this opportunity of recording some comments.

The Amorphous Metal Theory of Beilby. To my regret I am unable to sympathize with this theory, which, as the authors suggest, gives the only completely satisfactory explanation of the phenomena of the strengthening of metals by cold-work. First, I doubt whether the amorphous metal theory might justly be called a "theory" at all. In advancing a theory, a fundamental supposition is made, which by logical reasoning leads to conclusions controllable by observation.

The amorphous metal theory necessitates quite a number of independent suppositions: (1) The existence of the "amorphous" phase. (2) Different assumptions as to the properties of this phase, which is assumed to be hard, of great strength, to have fluid characteristics, to be soft at elevated temperatures and so on. In short, all the properties which can be observed in the metal itself are, as circumstances require, attributed to this hypothetical phase. Now, it is a somewhat unsatisfactory "explanation," to explain the properties of a substance as a whole by attributing the same properties to a hypothetical part of it. The amorphous theory might thus be termed a *pars pro toto* theory.

However this may be, there is a serious objection to this theory. It can explain the fact that a metal which has been stressed in tension beyond its yield point will after unloading and loading anew in tension exhibit a higher yield point, or, in other words, be strengthened. Now it is a known fact, established by the research work of Bauschinger, that a metal which has been stressed in tension beyond its yield point, has its original yield point in compression lowered, and *vice versa*. Cold-work in tension thus can effect strengthening in tension (hardening), but, on the other hand, cold-work in compression causes weakening (softening), when tested in tension. I should like to know how this well-established phenomenon could be explained by the amorphous theory without starting some new assumptions *ad hoc*.

This curious behavior of metals led me to the theory of "latent elastic strains" which is outlined in *Metall und Erz*, 1918, Nos. 22 and 23, and more completely¹ in the *Festschrift der Kaiser Wilhelm Gesellschaft zur Forderung der Wissenschaften*, 1921, p. 121, entitled "A Theory of the Strengthening of Metals by Cold-Work."

As to the boundaries between neighboring crystal grains, I am convinced that in them the arrangement of the particles of the space lattice will be different from the arrangement of the particles in the interior of the

crystal grains. A field of forces will act between the surface layers of contiguous crystals and the particles will take positions along the lines of force. This forced or restrained state of the substance along the boundaries seems to me to have close resemblance to a state of elastic strain. In so far I agree with the authors that these boundaries play an important rôle in the behavior of the metal.

Provided there is no foreign matter inclosed between neighboring grains, I cannot see any necessity to suppose these boundaries to be amorphous, or liquid, or undercooled, and I oppose this view for the same reasons which hinder me from denoting by the word amorphous a crystalline substance which is slightly deformed under elastic strain.

Troostite, Osmondite, Sorbite. The authors join the very generally accepted opinion that these constituents represent nothing more than different degrees of subdivision of the cementite particles in a ferrite-like groundmass. Some years ago I called attention² to the maximum of solubility exhibited by steel hardened and tempered at 400 deg. C. (exhibiting a structure called osmondite) to the maximum of dark coloration on etching and to the greatest carbonaceous residue on dissolving such steel in dilute acids. Prof. Benedicks tried to explain this behavior by drawing analogies with the phenomena observed in colloidal solutions of solid bodies in liquids. But his argument, though ingenious, appeared to me somewhat unconvincing and my doubts have recently been strengthened by the magnetic experiments of Saizo Saito³ which led this author to the conclusion that the transitional constituent "osmondite" in fact contains free carbon.

Martensite Is Alpha Iron. The authors conclude that the magnetism of the martensite suggests the presence of crystalline, magnetic (alpha) iron. Most metallographers are now inclined to believe that there is no difference between alpha and beta iron, but that the critical range A_1 is nothing more than the temperature at which alpha iron loses its magnetism on heating and regains it on cooling, without any change of phase. Now, what would happen, if, by any treatment, it was possible to conserve gamma iron below A_1 ? Could not then the gamma iron have a magnetic transition point of its own, so that the gamma iron could be ferromagnetic below some definite temperature? Indeed, Prof. Honda⁴ found magnetic transformations in carbon steels at temperatures above A_1 —that is, when the iron is undoubtedly in the gamma state.

The results of X-ray spectrometry alluded to by the authors would no doubt give valuable evidence as to this question. I look forward with the greatest interest to the publishing of the details of these experiments.

What the X-Ray Spectrometer Tells About the Structure of Solid Solutions

To the Editor of Chemical & Metallurgical Engineering

SIR:—In referring to Haakon Styri's splendid notes¹ on the paper of Jeffries and Archer² on "The Slip Interference Theory of Hardening," it is mainly with the idea of throwing a little light upon the matter of the space-lattice conception of solid solutions. Mr. Styri has struck upon those points in the theory which have formed the basis of most of the criticism that has come to the writer's attention.

It is undoubtedly true that the X-ray spectrometer would fail to find a small amount of cementite even if it were present in austenite as such. Indeed as the writer has shown the pattern is only faint in a white cast iron whose cementite content may be quite high. Furthermore, in examining any crystalline matter composed of iron and carbon the pattern is that of the iron atoms, substantially as if the carbon were empty space. The disparity of atomic weight is responsible for this phenomenon. Nevertheless there is great cause to regard austenite as a solid solution of carbon in gamma or face-centered iron.

Many experiments have shown that when the microscope and the equilibrium diagram indicated that a solute metal exists in solid solution in a solvent metal the X-ray spectrometer shows that the average spacings between the atomic layers have not changed (center to center) from those in the pure solvent and that the solute atoms simply replace atoms in the solvent lattice. The extent of the solubility is indeed in a sense a measure of the similarity in volume and electronic distribution of the two kinds of atoms. Thus the cube edge of the "crystal cell" of copper has not changed by the addition of 30 per cent of zinc. Beyond this amount there seems to be such force distortion in the lattice that further additions of zinc form a different lattice whose interatomic forces are compatible with stability. In different alloys this may or may not represent a compound in which a definite number of each kind of atoms forms the basis of the "crystal cell." As solute is added the volume of the solid solution naturally increases in proportion to the atomic volume of the solvent, multiplied by the number of atoms of solute incorporated.

By analogy, cannot carbon atoms replace iron atoms in austenitic iron? The writer first sought to explain the solution of carbon (regardless of state) in austenite by placing the carbon atoms in the interatomic spaces—the tetrahedra of the face-centered lattice suggesting a stable location for the supposedly tetrahedral carbon atom—but the volume increase forbids consideration of this easy solution. Indeed the suggestion that volume increases with addition of cementite to austenite supports our conception admirably.

So then, if the carbon atom in austenite were compelled to be surrounded by three iron atoms in some manner to constitute Fe_3C (or perhaps Fe_3C_2) we should certainly have a discontinuity in the austenite lattice. In the course of the same investigation in which the writer, under the direction of Dr. Jeffries, showed that manganese steel, nickel-iron and hot iron were all face-centered cubic in character, some information regarding cementite was obtained—namely, that there are spacings in the cementite lattice which could not pass

through the austenite lattice. Hence even a single "crystal cell," even if it were the simplest molecule, could not diffuse through austenite and the carbon atom would have to progress by continuous distortion of the lattice, constantly divorcing its iron partners and setting up new distortion. But even by this process we have been forced to picture carbon atomically dispersed, which seems to be the point which is not looked upon with favor by those who object to the idea that the solution of cementite in iron is a true solid solution. The fact is, we must regard atoms—not molecules—as the basis of crystal structure; the bricks, if you will, that build the walls of the crystal. The bricks are not alike, but fit together to form a stable whole.

In all fairness it should be said that the author finds certain strong lines in his cementite pattern to match lines in austenite. This may indicate that austenite has stability approaching that of the compound, but it does not alter the fact that all specimens of cementite do show the same very complicated pattern with some large spacings. Frankly, the "puzzling out" of the cementite lattice progresses very slowly and is very baffling. A few large crystals of pure cementite suitable for examination by the original Bragg method would greatly facilitate a solution of its structure.

Picturing here and there a carbon atom replacing an iron atom in austenite, quenching merely permits the allotropic change, leaving the carbon atoms *in situ* in martensite. The body-centered iron lattice in martensite, marvellously fine grained, is no doubt subjected to enormous force distortion by the presence of the carbon still atomically dispersed. Carbon then, as far as itself is concerned, is very like a compressed monatomic gas and could very easily, it would seem, form hydrocarbons with the "nascent" hydrogen formed during solution by acid.

The writer does not feel qualified to discuss the other extremely interesting points in Mr. Styri's paper and has in mind merely the idea of adding possibly a few details of the atomic structure phase of the new theory.

Cleveland, Ohio.

The Use of Inert Gas for the Prevention of Explosions

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the use of inert gas for the prevention of explosions and fires, as described by Edward F. White in the Sept. 14 issue of your journal, may I call attention to the fact that the Lewis Recovery Corporation has United States and foreign patents for the use of flue gas as a carrier for the vapors of volatile solvents used in coating, impregnating or treating fabrics or other materials?

This corporation has had solvent recovery plants embodying this principle in continuous operation for over four years with entire absence of fires and explosions. These plants are recovering solvents such as gasoline and benzene in industries in which fires have been notoriously frequent. Indeed, a fire outside the inclosed solvent-using equipment in one of these plants failed to ignite the flue gas-solvent vapor mixture within, although it destroyed everything outside. No difficulty has been encountered in operating with a maximum oxygen content of 3 per cent. This gives a factor of safety of 4, as 12 per cent oxygen is required for flame propagation in hydrocarbon vapors.

Lewis Recovery Corporation
Cambridge, Mass.

Joseph William Richards In Memoriam

DR. JOSEPH WILLIAM RICHARDS, professor of metallurgy at Lehigh University, died at his residence, 231 East Market St., Bethlehem, Pa., on Wednesday, Oct. 12, 1921, at 9 a.m., from heart failure. Impressive funeral services were held on Saturday following at Packer memorial chapel of Lehigh University, where a large number of friends, among whom were the leading chemists and metallurgists of America, gathered in honor of his memory.

J. W. Richards was born in Oldbury, England, fifty-seven years ago, on July 28, 1864, and was brought to this country when very young. He was graduated from the Central High School of Philadelphia, Pa., in 1882 with the degree of Bachelor of Arts (A.B.) and entered Lehigh University in September of that year. He was graduated from Lehigh University in 1886 with the degree of Analytical Chemist, and was awarded the degree of Master of Science (M.S.) in 1891 and that of Doctor of Philosophy (Ph.D.) in 1893. In September, 1887, Dr. Richards was appointed assistant instructor in metallurgy and blowpiping at Lehigh University, and he served continuously at the university from that time to his death in the following positions: Instructor in metallurgy, mineralogy and blowpiping, 1890-1897; assistant professor, 1897-1903; professor of metallurgy, 1903-1921.

Dr. Richards was one of the foremost engineers of the country and had an international reputation in various branches of metallurgical technology. His services were widely sought as legal expert in chemical and metallurgical cases. He was a member of the U. S. Assay Commission, 1897; representative of the Franklin Institute to the International Geological Congress held in Russia in 1897; member of the jury of awards, department of chemistry, of the National Export Exhibition, Philadelphia, in 1899; member of the jury of awards and chairman of the metallurgical sub-jury, Panama Pacific International Exposition, 1915; member of the U. S. Navy Consulting Board, 1915-1918. He was a member of the Franklin Institute, Philadelphia, president of the chemical section 1897, 1899, and professor of electrochemistry of the Institute 1907-1910.

Always of an independent and original turn of mind, it was not surprising to find Richards among the "insurgents" from the American Chemical Society and the American Institute of Electrical Engineers who met

in Philadelphia nearly twenty years ago to form the American Electrochemical Society; indeed, he was the first president. Many of the conservatives decried the movement, on the basis that there were enough national societies already, but the independents persisted. Since the first, the Electrochemical Society has been unique in the hearty friendliness of the gatherings, much in contrast with the habitual secrecy and reserve supposed to permeate the industry. On the other hand, the influence of example has not been without value to the tone and activities of each of the older societies. Dr. Richards' interest has been continuous. President for the first year of its existence, he became secretary in 1907, an office he has filled since that time.

A few months after the electrochemists formed their society, a small group of enthusiasts gathered together in a certain public house in Philadelphia, prominent among

whom were Dr. Richards, W. D. Weaver, then Editor of the *Electrical World*, Carl Hering, and E. F. Roeber. Talk ran upon the need of a publication reflecting the aims of the new society, and it was agreed that such a magazine should be published. Unfortunately, or perhaps fortunately, the new society, numbering only 200 or 300 members, had not the funds for the venture, but Weaver promised to interest Mr. McGraw in the project, if possible. In this he was successful, and the Electrochemical Publishing Co. was formed, with Dr. Richards as president, a company which with Dr. Roeber as editor on Sept. 1, 1902, started publishing *Electrochemical Industry*, the forerunner of CHEMICAL & METALLURGICAL ENGINEERING.

Dr. Richards was no dummy president. His interest in the details of the publication was intense for several years. Further-

more, he was one of the principal editorial contributors in the first volumes, publishing many notable articles on electrometallurgy as practiced both here and abroad. His important work on *Metallurgical Calculations*, which has become standard and has had such a wide circulation in several languages, was published serially in *Electrochemical Industry*.

His other books include a treatise on Aluminum, and several translations, principal among which is "Cementation of Iron and Steel" from the Italian of Federico Giolitti. His contributions to the technical press and many scientific societies are legion.

Dr. Richards was fortunate in selecting teaching as a profession, and his influence on American technology, transmitted through his students, will be unending. They especially will mourn the passing of a helping friend and a true gentleman.

JOSEPH WILLIAM RICHARDS

Studies in Colorado Shale Oils—A

Secondary Oils Obtained From a Representative Colorado Shale Oil by Successive Distillations at Atmospheric Pressure—Character and Composition of These Decomposition Products and of Their Parent Material

By ARTHUR J. FRANKS

IN TWO recent preliminary papers¹ under this title the author presented elementary data on a number of Colorado shale oils and their fractions. The results of this work have shown that the heavy fractions of these oils are unstable and crack easily on distillation at atmospheric pressure. The decomposition is attended by the following very marked phenomena: (1) a lowering in specific gravity; (2) an increase in saturated hydrocarbons; and (3) a considerable loss of nitrogen and sulphur, as well as a decided change in their distribution. The increase in saturation was accounted for by the decomposition of the heavy, unsaturated and unstable compounds containing sulphur and nitrogen, and perhaps oxygen. But since such a phenomenon is not in accord with the theories and results prevalent in petroleum practice and because the evidence already presented was not conclusive, it was decided to extend the scope of these preliminary investigations in order to obtain further data, either in support of or in contradiction to the theories already suggested.

SCOPE OF THE PRESENT INVESTIGATION

The purpose of the present work was to study, by means of careful analyses, the changes produced in the fractions of a representative Colorado shale oil by repeated distillations at atmospheric pressure, to endeavor to verify previous data with the hope of proving conclusively that new saturated hydrocarbons were formed as a large portion of the products of cracking and that their source was the heavy compounds soluble in concentrated sulphuric acid, and, if possible, to throw further light on the general character and composition of these decomposition products and their parent material.

This investigation was conducted along the same general lines as in the previous studies.² Two series of distillations were made. The first involved four successive distillations of a single sample of oil into 10 per cent fractions. The changes in these fractions were determined by the means of measurements of specific gravity, saturation, temperature of distillation and amount of decomposition, and by analyses for sulphur and nitrogen. On the basis of the behavior of the oil, as determined by these changes in the 10 per cent fractions, conclusions are to be drawn as to some of the general characteristics of the oil as well as its probable composition. A second series of distillations and analyses were made on another sample of the same oil to prove definitely that saturated compounds formed a large part of the products from the cracking of some of the heavy, unsaturated and basic fractions, to provide a sufficient amount of cracked distillate for examination and to serve as a general check on the first part of this work.

The oil upon which this investigation was made was chosen because it was regarded as representing a typical product from Colorado shales of the De Beque region. It was made in a Ginnet retort and was obtained through the courtesy of the Monarch Shale Oil Co. A 1-gal. sample was taken from a 10-gal. can of this oil which had been allowed to stand undisturbed in the laboratory for two weeks in order to permit most of the suspended water to settle out. The sample was thoroughly mixed by long shaking and a 4-oz. portion withdrawn for analysis. The results of this analysis are:

Specific gravity.....	0.909	Nitrogen, per cent.....	1.992
Saturation, per cent.....	20.8	Water, per cent.....	0.13
Sulphur, per cent.....	0.72	Initial boiling point, deg. C.....	70

OUTLINE OF THE INVESTIGATION PROCEDURE

All distillations were made in Pyrex distillation flasks at a rate which was maintained constant throughout the progress of the distillation by constant and extremely careful regulation of the gas flames. Naked flames from Meeker burners were used as the source of heat. The sizes of all fractions are expressed on the basis of the original oil volume and not that of the oil distilled. The vapor temperatures were measured by a 400 deg. C. thermometer and are uncorrected for the emergent stem. The same one was used for all distillations in order that the results might be strictly comparative.

All specific gravities are expressed at 25 deg. C. and were obtained from the Baumé values taken with a hydrometer. The conversions were made from standard tables. The same hydrometer was used for all the determinations.

The water, initial boiling point (i.b.p.), saturation, nitrogen and sulphur were determined as described in former papers.³ A modified Kjeldahl method was used in obtaining the nitrogen and a modification of the Parr sodium peroxide fusion method for the sulphur. All analyses of the crude oil and fractions were made in duplicate with extreme care. Where the results failed to check within reasonable limits the analyses were repeated and averages taken as the true values.

METHOD OF PROCEDURE FOR THE FIRST SERIES OF DISTILLATIONS

In the first distillation it was attempted to separate the oil into 10 per cent fractions with as little decomposition as possible without resorting to the use of either a vacuum or steam. A 1,500-c.c. portion of the well-mixed sample was distilled to dryness from a weighed 2-liter distillation flask at a rate of about eight drops a second. When the vapor temperature reached 300 deg. C. hydrogen gas (obtained from a cylinder) was introduced slowly in five fine streams through a perforated tube which extended to the bottom of the flask.

¹CHEM. & MET. ENG., vol. 24, No. 13, March 30, 1921, p. 561 and vol. 25, No. 2, July 13, 1921, p. 49.

²Loc. cit.

³Loc. cit.

FIG. 1. TEMPERATURE CURVES

As the distillation continued, hydrogen was admitted at an increasing rate, which reached about 25 liters per 100 c.c. of distillate near the end. The rate of heating and the amount of hydrogen used were so controlled that no appreciable amount of vapor issued from the condenser. After the distillation was finished the flask was cooled and weighed. The increase in weight gave the amount of coke produced by decomposition of the oil.

Two composites were then made from two-thirds (100 c.c.) of each of the 10 per cent fractions; one contained the first three and the other the last seven fractions. The remaining portions of each fraction were then analyzed. The results appear under "1" in Table I.

DISTILLATION OF THE COMPOSITES

The two composites were then distilled separately to determine their stabilities. It was also desirable to remove the lighter oils in order that the changes in the heavy oils might be more marked. The result of such procedure will be obvious from a glance at the curves in Figs. 1 to 4.

The 300-c.c. light oil composite was again distilled at a constant rate from a 500-c.c. distillation flask into three 10 per cent fractions of 100 c.c. each. The last fraction contained only 98 c.c., since it was impossible to drive over all of the oil. This introduces no appre-

ciable errors in the analysis, however. The same analyses as before were made on each fraction. The results are given under "2" in Table I. No further distillations of the light oil were made, since changes other than those due to refractionation are not apparent. The remainder of this part of the investigation was conducted on that portion of the oil above and including the 40 per cent fraction.

The heavy oil composite (623 c.c.) of the seven fractions from "1" was distilled from a weighed 1,000-c.c. distillation flask into 10 per cent fractions of 100 c.c. each. The distillation was carried to dryness, at a rate of two drops per second, as described in a former article.⁴ The weight of coke was obtained from the difference in weight of the flask before and after distillation. Three-tenths (by volume) of each of the cuts

FIG. 2. SPECIFIC GRAVITY AND SATURATION CURVES

were reserved for the usual analysis, the results of which are presented under "2" in Table I.

The remaining seven-tenths of each of the fractions from "2" (405 c.c.) were composited and distilled to dryness from a weighed 1,000-c.c. distillation flask at approximately the same rate and in the same manner as before. Ten per cent fractions (70 c.c.) were again taken and the coke determined. Three-sevenths of each

of these cuts were withdrawn and the same determinations made as for the other fractions. The results of the analysis appear under "3" in Table I.

The four-sevenths of the oil remaining from each of the "3" fractions (217 c.c.) were composited for the last time and distilled into 10 per cent fractions (40 c.c.) from a weighed 500-c.c. distillation flask. The rate of distillation was maintained at about three-fourths of a drop per second. The usual data were obtained on these fractions. The results are given under "4" in Table I.

FIG. 3. SULPHUR CURVES

METHOD OF PROCEDURE FOR THE SECOND SERIES OF DISTILLATIONS

The second series of distillations was carried out in a somewhat different manner. A 1,200-c.c. sample of the same oil was distilled from a 2-liter flask at a rate of four drops per second until 30 per cent (360 c.c.) had been condensed. The resulting fraction will be called "A" for the sake of convenience. The distillation was then stopped, the undistilled residue (hereinafter designated as fraction "B") allowed to cool, and a sample then withdrawn for analysis. A 490-c.c. portion of this residue was then distilled to dryness from a weighed 1,000-c.c. flask at a rate of two drops per second. The weight of coke was obtained by weighing and subtracting the weight of the cold flask. Vapor temperatures were read at every 5 per cent fraction, but no cuts were made. The whole distillate (hereinafter designated as "C") was then thoroughly mixed and a sample taken for analysis.

The heavy unstable oils present in B must have decomposed during this distillation, and whatever light oils were thus formed therefrom must have been left in C. Hence, 330 c.c. of C was then distilled from a 1,000-c.c. flask at a rate of two drops per second. As the vapor temperature reached 250 deg. C. the distillation was slightly retarded in order to permit a sharper separation of the oil boiling below 254 deg. C., at which temperature the distillation was discontinued. This distillate will be hereinafter referred to as "D" and the residue as "E." Obviously, D is a new, secondary product formed by the cracking of certain constituents originally present in B.

Determinations for specific gravity, saturation, sulphur and nitrogen were made on A, B, C, D and E. All analyses were made in duplicate. In addition to these analyses, determinations for aromatics and organic bases were made in A and D. The data from these analyses are given in Table II. The temperature curves are presented, together with those from the first series of distillations, in Fig. 1.

The aromatics were determined by the "aniline point" method developed by Tizard and Marshall.⁵ It depends upon the difference between the temperatures of mutual solubility of saturated hydrocarbons containing aromatics, and of those free from such compounds.

It was first necessary to remove from the sample to be analyzed all bases and unsaturated hydrocarbons by means of a thorough treatment in the cold with a liberal amount (about 200 per cent by volume in all) of 95 per cent sulphuric acid. The saturated hydrocarbons were allowed to separate, the tar was drawn off, the hydrocarbons poured into a small clean flask, and then carefully washed with a very small amount of water. Powdered anhydrous sodium carbonate was then thrown in to neutralize any acid remaining in the oil and to take up the water. After standing for about a day the oil should be neutral, clear and dry. An ordinary washing

FIG. 4. NITROGEN CURVES

with either water or alkali solution should not be attempted in the case of shale oil distillates, since persistent emulsions are formed which are separable only with great difficulty.

After obtaining the specific gravity, the aniline point was then determined on the saturated hydrocarbons by measuring a 10-c.c. portion into a large test tube from a pipette, adding 10 c.c. of freshly distilled aniline from another pipette, heating and stirring the mixture until complete solubility obtained, then slowly cooling and stirring and determining the temperature at which it became turbid. This temperature is the aniline point.

The remainder of the saturated oil was then sulphonated by shaking in the cold with a liberal amount of 98 per cent sulphuric acid for about 20 to 30 minutes, which treatment removes the aromatics. The hydro-

⁵J. Soc. Chem. Ind., 40, 20T, 1921.

carbons were then separated, washed and dried as before, and the aniline point determined. The percentage of aromatics by weight was obtained from the difference in aniline points by the use of a curve prepared by Tizard and Marshall.⁶ Since the saturation and specific gravity of the oil and the specific gravity of the saturated hydrocarbons were known, the percentage by weight of aromatics in the original sample was easily calculated.

The bases were determined by measuring the absorption of the oil by dilute hydrochloric acid. Ten c.c. of the oil was measured into a graduated 15-c.c. centrifuge tube and 3 c.c. of HCl (1 part conc. acid to 4 parts of water) added. The tube was stoppered, well shaken and centrifuged until separation of the two liquid layers was complete. From the amount of oil absorbed by the acid the volume per cent of bases was calculated.

The unsaturated compounds are expressed in per cent by volume and were calculated as the difference between 100 and the sum of the bases and saturated hydrocarbons.

FACTS DEDUCED FROM THE TABULATED DATA AND GRAPHS

The data presented in the tables and represented graphically by the curves verify the results of previous work, as well as many expectations. In general it may be said that the light oils (boiling below 270 deg. C.) are very stable and suffer no appreciable alterations on distillation other than those due to changes in distribution of some of the compounds obtained by a higher degree of fractionation. The heavy fractions of the crude oil, on the other hand, are not stable, and during a single cracking distillation suffer extensive decomposition. This phenomenon has already been mentioned by the author in the two previous papers mentioned above and by C. W. Botkin.⁷ The very heavy end portions of the crude oils are so unstable that they decompose even when a large quantity of an inert gas (such as hydrogen) is used during the distillation. This is obvious from a comparison of the analysis of the heavy oil composite from the first distillation with the analysis of the undistilled residue *B*. The data in Table III show that, generally speaking, about half of the unstable constituents of the heavy oils are of this type.

After one cracking distillation, however, the oils produced and those escaping decomposition are fairly stable.⁸ Yet further distillations do effect appreciable changes in the oils, as the curves and especially the calculations from the data (Table III) show.⁹ At the end of four distillations the heavy fractions (above 270 deg. C.) of the crude oil, with the exception of saturated hydrocarbons, had decomposed to such a great extent that the resultant distillates seemed to be virtually new oils, composed largely of products from the cracking of those fractions. It will be shown later that this is actually the case.

The temperature curve (Fig. 1) constitutes a valuable index of the general course of the changes produced in the oils by the successive distillations. The temperatures at which 10 per cent cuts were made are plotted as

ordinates and the per cent distilled as abscissas. These and all curves are drawn through the mean values wherever the points fail to strike a smooth curve. In most cases, however, the curves pass through the points determined experimentally. The curve for the first distillation lies above the others because of the great rate at which the liquid was distilled in the attempt to prevent decomposition as far as possible; hence the fractionation was poor. This is verified by curve 2 for the second distillation of the light oil. The curves for the products *A* and *C* are representative of results secured by the standard method⁹ of distillation adopted in this work. Curve 2 for the heavy oils shows that much decomposition and the formation of a large portion of the light oils occurred during the first distillation. Curves 3 and 4 indicate further decomposition and light oil formation, as well as increased stability of the distillates. It is obvious that the 30 to 46 per cent fraction (65 to 276 deg.) from the fourth distillation consists of oils produced by the cracking of unstable constituents of the crude and not present originally therein.

The specific gravity curves (Fig. 2) merely confirm the conclusions drawn from the temperature curves.

The curves in Fig. 2 representing the distribution of saturated hydrocarbons show marked resemblance to the specific gravity and temperature curves. This verifies the qualitative relationship stated by the author⁹—namely, that the percentage saturation of the 10 per cent fractions decreases as their specific gravities and

TABLE III. PERCENTAGE LOSSES AND INCREASES IN SATURATION OF DISTILLATES

Kind of Loss	Distillation				Total 1-4	B-C
	1	2	3	4		
Total weight.....	9 20	5.91	3.97	1.82	20.90	16.3

Increase in sat., per cent.	44.7	16.1	5.0	—2.0	63.8	51.0

vapor temperatures increase. This relationship is well illustrated, especially by the curves for those fractions near the end of the distillations.

The sulphur curves in Fig. 3, in which the percentages of sulphur are plotted as ordinates and percentage distilled as abscissas, certainly confirm the results of and conclusions drawn from previous work relative to the distribution of sulphur and its relation to various properties of the distillates. They are very similar in form. This is all the more remarkable when it is considered that all of these curves either pass through or strike very close to the points determined by analysis. In no case are the differences greater than possible errors in the analyses themselves. The data and curves confirm the deductions arrived at in the preceding paper—namely, that the cracking causes a considerable loss of sulphur, but only a small lowering of the percentage in the resulting products, and that if most of the cracking is prevented the sulphur decreases regularly in the heavier distillates, as a part of curve 1 shows. Since decomposition began after the 80 per cent fraction, the balance of the curve is forced downward. The small difference between curves “3” and “4” indicate that although most of the cracking had occurred in the first two distillations there is still a little decomposition even

⁶Ibid., 22T.

⁷CHEM. & MET. ENG., vol. 24, No. 20, May 18, 1921, p. 876.

⁸Botkin (CHEM. & MET. ENG., vol. 24, p. 879) states: “Compared with the first distillation, the decomposition during the second and third distillations is very slight, occurring only at higher still temperatures when the distilling flask is nearly dry and probably at a temperature exceeding that indicated by the thermometer. This shows a high stability for the heavy portions of the once-run oils . . .”

⁹CHEM. & MET. ENG., March 30, 1921, p. 561.

after a third distillation. The amount of sulphur lost by the fourth distillation is, however, not great (see Table III), which shows that most of the unstable sulphur compounds had been decomposed in the first distillations and that the new compounds and those remaining are quite stable. The fact that all the sulphur curves turn downward near the end shows that the very heavy, last oils contain a little less sulphur than the less heavy fractions.

The nitrogen curves in Fig. 4, in which the percentages of nitrogen are plotted as ordinates and the percentages distilled as abscissas, are a great aid in following the course of the changes in the oils. Since the amount of nitrogen is relatively high, determinations can be easily and accurately made, and especially because most of the heavy nitrogen compounds seem to be sensitive to heat and easily decomposed. The curves furnish further evidence in support of the conclusions drawn from the data in the preceding paper relative to the distribution of the nitrogen and the forms in which it occurs, and also confirm the deductions from the other curves presented in this communication.

It is rather surprising to find the distribution of the nitrogen so consistent and the changes in distribution so abrupt. The persistence of straight lines which represent uniform increases in nitrogen at four different rates in the distillates cannot be ignored, although their significance is not clear. The curves suggest the presence of four different series, or classes, of nitrogen compounds. No other explanation seems possible for these sharp turning points in the curves and for the uniform rates at which the nitrogen increases in the different fractions. Most of the nitrogen in the fractions boiling up to 300 deg. C. is present in the form of basic compounds, since but little nitrogen is left in these distillates after a treatment with dilute hydrochloric acid. Much basic material is also present in the heavy oils, but a large amount of the nitrogen seems to be present in the form of heavy oils containing sulphur and resembling the heavy fractions of asphaltic petroleum. Some of these nitrogenous, asphaltic oils seem to be quite stable, but the others (which are heavier) are not. This accounts for three main classes of compounds. Since there must be more than one class of nitrogen bases, the presence of a fourth series is almost certain. Many others may be present in such small amounts, or they may be distributed throughout the oil in such a manner as not seriously to effect the general distribution of the nitrogen.

Part B of this article will be published in a subsequent issue.

Cement Industry in the Philippines

The town of Naga, in the Island of Cebu, is now conceded as the best field for a cement industry in the Philippines, according to the Bureau of Science, Manila. Both the chemical and grinding tests on raw cement material produced in the field have been highly successful and point to the feasibility of a cement venture on a large scale.

The field is situated near coal mines from which a suitable supply of fuel may be run to the cement plant by gravity.

The National Cement Co., mostly owned by the Government, will in a short time erect a cement plant in this locality, it is reported.

Strengthening Metals by Cold-Work

BAUSCHINGER'S numerous experiments on cold-worked metals proved that if a test-piece be overstrained in tension beyond the original elastic limit, $+\sigma_e$, it thereby acquires a higher elastic limit in tension, but a lower elastic limit, $-\sigma_s'$, in compression (and *mutatis mutandis*). Thus cold-work in tension strengthens in tension but weakens in compression, and *vice versa*. In general the original properties return after heating beyond a "temperature of restoration," varying with the metal. In tin and lead, for instance, it lies near atmospheric. (Such metals are excluded from consideration in what follows, since working at ordinary temperatures causes no change in properties.)

Prof. E. Heyn attempts to explain the nature of these changes.¹ He says that deformation may be elastic or plastic. Within the limits of elasticity, the outer forces are balanced by those set up by the small displacements of the "smallest particles" (Heyn does not call them atoms or molecules) from their mean positions in the space lattice. Release of stress is accompanied by regeneration of the work of deformation, and the process

FIG. 1. IDEAL STRESS-STRAIN DIAGRAM ON RELOADING IN TENSION

is reversible. True plastic deformation is visualized by Prof. Heyn thus: Materials stressed beyond the "limit of flow" act like clay, the tiny particles migrate from one position of stability to another, and yet another. Continual flow takes place without increase of stress; increasing the force only increases the rate of flow. Release of force causes no restoration of shape or energy; the process is not reversible.

Under these suppositions an ideal stress-strain diagram should start from the origin and rise straight (by Hooke's law) to the elastic limit, (OS' in Fig. 1) then proceed horizontally along S'T to fracture. However, the actual diagrams are essentially different. The proportional limit is reached before the "limit of flow," and the latter is accompanied by no sharp break in the curve at S, only a very small radius of curvature, except with the iron alloys and a few others. Prof. Heyn says this early deviation from elastic behavior is due to true plastic deformation at defects and minute cavities acting as internal notches. Once the limit of flow is passed, added stress must be imposed to continue the elongation, even up to fracture, as shown by the curve SA, because in metals the deformation is accompanied by rupture of the crystallites into

¹*Metall und Erz*, 1918, Nos. 22 and 23, and *Festschrift der K. Wilhelm Gesellschaft zur Förderung der Wissenschaften*, 1921, p. 121.

smaller blocklets; the body of these still act in an elastic manner, even though they are sliding past each other at their boundaries as in true plastic deformation, therefore added loads must be imposed to overcome the elastic resistance of the blocklets still remaining intact. He insists that such phenomena can occur in a pure metal containing but a single phase.

If a tension test-piece is stressed somewhat beyond the limit of flow, say to point *A* (Fig. 1), and the load removed, a certain amount of contraction *CJ* may be measured, a quantity which varies somewhat with the speed of release and upon aging. The permanent set *OC* determined immediately may therefore consist not exclusively of plastic deformation, but in small part of elastic deformation held latent by internal forces.

Reloading for a second time, it is found that the limit of flow has increased. Yet if the permanent set consists entirely of plastic deformation, it would seem that the smallest particles should have returned on unloading to their original distances between mean positions, and apparently should require the original stress to restart plastic flow, and not resist a somewhat larger one. Hence Heyn returns to the assumption given in the preceding paragraph, that overstrained metal retains in addition to much pure plastic deformation a certain amount of elastic elongation or strain ϵ_l and also a corresponding stress in tension σ_l , which is in equilibrium with some internal force similar to frictional resistance. The imposed load P/f is equal

FIG. 2. IDEAL STRESS-STRAIN DIAGRAM ON RELOADING IN COMPRESSION

to the unit stress σ when the unloaded bar is free of original strain, or when release of outer load is accompanied by no latent stress σ_l . He likens the action to that of a rod of purely plastic substance like plasticine in which is embedded a multitude of fine spiral springs, which act in an elastic manner even when the piece is stressed above σ_s , the limit of flow. If this rod is rolled out, the springs attempt to return to their original position but are restrained by their anchorage.

Using these ideas to analyze the action on release of a tension test-piece loaded to a point *A* (Fig. 1), Prof. Heyn notes that at first the internal stress remains

constant at σ_l (and the corresponding deformation at *OJ*) even while the imposed load P/f is decreasing. When $\sigma_A - P/f$ becomes sufficient to overcome the internal resistance w , the test-piece shortens an amount proportional to the further decrease in loading. The curve representing the relation between elongation and external load (the $\epsilon, P/f$ curve) becomes *ABC*; the ϵ, σ curve (or that between elongation and internal stress) for the corresponding time is *AD*, parallel to *BC* and separated by a constant distance, σ_l .

On reloading, the rod does not elongate until the outer force P/f becomes equal to the internal resistance counteracting the latent stress σ_l . After that, Prof. Heyn states, the rod acts exactly as it did on first loading—i.e., the curve *OSA* begins from point *D* as origin and follows *DEG*. In this the $\epsilon, P/f$ curve is *CDEFG*. The ϵ, σ curve is a parallel curve, σ_l below, or what is the same thing, curve *DEFG* with horizontal *DK* for x -axis.

The so-called strengthening, therefore, merely consists of moving the limit of flow from the load *S* to the load *F* (Fig. 1), on the original curve *OSA*. He also believes that this strengthening is fictitious, since he measures the true internal stress σ on reloading from abscissa *DK*, and its real magnitude is the same in the second as in the first reloading. In his words: "The essential point is that the theory of latent stresses explains the loop formed by experimental stress-strain curves on repeated loadings." The form of the loop *ABCD* naturally varies with the circumstances.²

When loading the overstrained bar in compression, certain phenomena occur which may best be visualized by considering the overstrained bar as a complex of springs called α remaining in tension (by latent stress) and others called α' in compression (for equilibrium). Further it is assumed that a stress-strain diagram in compression would be the same shape as in tension, merely rotated 180 deg. about the origin. After release from overstrain springs α are in tension equal to $+\sigma_l$, and springs α' are in compression equal to $-\sigma_l$. As loading progresses the compression on springs α' continually increases and at *F*, the limit of flow, it is equal to $-\sigma_l - P/f$ (the distance *MF*, Fig. 2). In other words, draw a stress-strain curve in compression downward from *Q* as origin, and it will correspond to the curve derived from experiment. Such construction also shows that the hypothesis of latent stress explains why the limit of flow in compression, after an overstraining in tension, lower in numerical value than the original limit of flow in tension.

Recognizing the inconsistency of using a plastic mass to restrain his imagined springs when reloading in tension and replacing this plastic mass by springs in compression when loading in compression, Heyn imagines the latter to be incapable of taking stress except in compression. Thus they would have no influence on a second loading in tension.

Since either tension or compression causes the same kind of failure in crystalline metal—namely, by shear—the resultant deformation on cold-work is always of the same nature. By the theory of elasticity, such deformation is accompanied by an increase in volume; it has been found experimentally that cold-work of any kind is accompanied by a decreased specific gravity, according to theory.

Causes of High Top Heat in the Blast Furnace

Charts Recording the Temperature of Waste Gases Are of Value in Controlling Furnace Operations, Indicating Especially Clearly the Exact Time When Charging Is Done and if the Charge Is Alternately Hanging and Slipping

By WALLACE G. IMHOFF

IT IS extremely interesting to study the operation of the blast furnace from the viewpoint of the top heat. This feature is not of minor importance, but really is deserving of careful consideration, for by thoroughly understanding the causes which effect the top heat at least one result will be smoother furnace operation.

In order to control the top heat all the conditions which effect it should be known and thoroughly understood. Some of the most important features and indications of high top heat are listed in the captions below, and discussed in some detail.

HIGH WIND

For a given set of furnace conditions only a certain volume of wind can be blown in order to maintain a state of equilibrium. If the volume of wind is decreased, then the furnace will at once respond by becoming hotter in the bottom, or if the volume of wind is increased, the furnace will at once respond by becoming colder in the bottom. Therefore a very important feature is to know just how much wind to blow into a furnace to give the smoothest operation. All these features seem so simple that they are not even important enough to bear discussion, yet in practice they are not so thoroughly understood.

Suppose, for example, we try to increase our tonnage by increasing the wind. At first perhaps there does not seem to be any appreciable difference in the operation of the furnace, but by and by the reserve heat in the furnace has been exhausted and we note as time goes on that our top heat is gradually beginning to rise.

In a short time the furnace seems to be getting cold in the bottom, although the top heat continues to remain high. As a matter of fact, with the reserve heat gone the bottom is now blown cold and the fusion zone has risen from the hearth to the mantle or higher, thus causing the continued high top heat.

LOW STOVE HEAT (COLD AIR)

One of the commonest causes of a high top heat is the continued use of cold air. At this time we generally have present an extremely hot bottom, or a bottom that is at least hotter than is desired. This would be the time to increase the wind and get more tonnage, but as a matter of fact cold air is generally run in with the stove heat to lower the hearth temperature. The cold air has two effects—it reduces the hearth temperature to such an extent that it throws the silicon into the slag as silica, and thereby frees the sulphur; and second, it raises the top heat.

The first feature may often be desired to obtain better driving, especially if the furnace is hanging, but it is accomplished sometimes only by extreme sacrifice.

With the rise in top heat the furnace often gets in such a condition that it has to be slipped to put in charges. This aggravates conditions already bad and finally the furnace goes off entirely.

Cold air should seldom be used. The logical way to cool the bottom down is to increase the wind a revolution or so, and when the iron desired is made, then cut the wind back to normal. The use of cold air does not seem to be understood from another angle, and that is that it is often left on too long, throwing the furnace violently cold. Great judgment must be exercised in running the stove heat down with cold air that it be shut off before the cooling effect has gone too far.

LETTING THE FURNACE HANG A LONG TIME

It is not a good policy to let a furnace hang longer than thirty-five to forty minutes. There are a number of reasons for this, the most important one being that it precipitates too much cold stock into the hearth and lower part of the furnace at once, and hence makes extremely irregular iron.

The continued hanging of the furnace is indicated by a gradual rise in top heat. This is noted by the saw-toothed top heat curve drawn with regular furnace operation, the rise being made during the intervals of filling, and the fall being caused by the cold charge. With smooth regular driving these saw-teeth on the curve are small and there are a large number of them, for the furnace is filled often and the top heat does not have a chance to rise very high before another cold charge is put in.

The longer a furnace hangs the higher the top heat will rise. This is shown by the very large saw-teeth on the top heat chart. Once the top heat has risen to a high temperature it is often difficult to get it back to normal again. By watching the indications shown on the top heat chart under various conditions the state of the furnace can be immediately seen. For example, suppose it hangs for an hour, slips 12 ft., and then starts to hang again. The top heat chart shows a smooth continued rise in temperature, then a gradual dropping off for an hour in steps represented by the lowering of the big bell to drop in a new charge. With each charge there is a step down. Finally the furnace is filled and when the filling ceases, the top heat curve again ascends in a smooth, rising, straight line.

A COLD BOTTOM

High sulphur may be caused by a shortage of lime, but another cause of more importance is a cold bottom. The hearth temperature is the indicator of the condition of the sulphur, and, *vice versa*, the sulphur is the indicator of the hearth temperature.

The top heat chart may show a very low top heat with a cold bottom, or it may be very high. In the first

instance the stack is cold all the way up and down and therefore a top heat of 200 to 250 deg. may be expected. On the other hand, a cold bottom may be due to a high fusion zone, in which case a high top heat will be recorded. For example, suppose we show an actual case of this type. At 5:45 a.m. the bottom was cold, as shown by the analysis of the iron, 0.64 silicon and 0.078 sulphur. Thirty-two extra coke were put in at 7:50 a.m. Before the coke went in the top heat was 350 deg. By 7:40 p.m. the top heat showed 650 deg., and the bottom was still cold due to the fact that cold air was run in to counteract the effect of the coke.

As a matter of fact, the coke burned in the middle of the furnace and the bottom remained cold. By examining the iron it will be seen that when the effect of the coke disappeared the furnace was in as bad a condition as before. The complete analyses are given below:

Time	Silicon	Sulphur	
5:45 a.m.	0.64	0.078	Cold
10:50 a.m.	0.80	0.057	
3:55 p.m.	1.13	0.042	Greatest effect of coke
8:35 p.m.	1.15	0.062	
1:00 a.m.	0.80	0.052	Cold

32 extra coke put in at 7:50 a.m.
Top heat at 5:45 a.m., 350 deg.
Top heat at 7:40 p.m., 650 deg.

This example shows clearly why the lining in some furnaces is so badly cut out above the mantle. The high fusion zone is indicated clearly by the high top heat and cold bottom. The use of cold air is one of the quickest and surest ways of raising the fusion zone.

HIGH SULPHUR

As stated above, high sulphur is caused by a cold bottom. By continually observing the top heat chart other features of interest are also to be seen at this time. In addition to the high top heat and high sulphur, generally there is a high blast pressure, sticking and hanging, and slow furnace driving.

The addition of a large amount of extra coke often raises the sulphur. This is shown by an example when thirty extra coke were put in at one time. The top heat curve showed very high peaks and the iron at cast time analyzed 0.54 silicon and 0.072 sulphur. Another example is of interest, as it shows the effect very strongly in the iron and also in the extreme rise and fall of the top heat curve. At 2:30 p.m. thirty-two extra coke were put in. The complete analyses of the iron show the effect of the coke:

Time	Silicon	Sulphur	
5:45 p.m.	0.54	0.060	Cold
10:30 p.m.	1.38	0.034	Coke
2:55 a.m.	1.53	0.244	Coke
7:50 a.m.	0.37	0.207	Cold

High-sulphur iron is often made on a hot lean furnace. This also is accompanied with a high top heat. An example of such a furnace is given below. The top heat was from 400 to 650 deg. all the time:

Iron		Slag		
Silicon	Sulphur	Silica	Alumina	Bases
1.83	0.038			
1.70	0.047			
1.72	0.053	35.86	13.68	48.21
2.31	0.053			
2.22	0.067			

The silica in the slag should be about 33.00 for 13.68 alumina and 48.21 bases.

Hanging and extra coke go hand in hand. On some

furnaces it is a normal thing to put two extra coke in after every slip. It is interesting to look at the effect of slipping with extra coke as seen by the top heat chart. The condition of a furnace was such that it was slipped at 5:10, 6:05, 6:10, 6:20, 7:30. Eight extra coke were put in at 8:25 a.m., eight at 12:10 p.m., sixteen at 3 p.m. and eight at 6:30 p.m. The top heat had been running along at about 350 deg. Just as soon as the extra coke took effect it raised to 400 and then to 550 deg.

Another example showing the relation of the top heat to slipping and extra coke is shown when the furnace was slipped at 12:45 a.m., 1:45 a.m., 2:30 a.m., 3:20 a.m., 3:45 a.m. and 4:35 a.m. Four extra coke were put in at 12:20, and twelve extra coke at 4 a.m. The top heat had been running uniformly around 350 deg. When the coke came down the top heat chart showed 350, 350, 400 and 500 deg. respectively.

These examples are sufficient to show that continued slipping with extra coke will raise the top heat. With furnaces in extremely bad shape the top heat has been seen at 1,250 deg. and from 80 to 120 extra skips of coke were put in to bring the furnace around. It is needless to say such cases are seldom encountered.

TOO MUCH ORE FOR STONE

A number of cases have come to notice where a high top heat may be caused by having too much ore on the burden for the amount of stone that is carried. Whether there is or should be any relation between the top heat and the amount of stone carried is a question, yet at times when a high top heat was observed it was noticed that the furnace needed more stone.

LIGHT CHARGES

The various methods of charging a furnace, the size of the charge and the method of filling are a broad subject in themselves. A feature of particular interest at this time is the fact that a high top heat was repeatedly observed with light charges. It seems that when a heavy charge is used the ore and the stone have a blanket effect of holding down the top heat, while with small light charges the stock becomes intimately or haphazardly mixed and the coke burns up through the charges above.

It is readily seen how a large heavy blanket of ore would tend to lower the top heat. In some instances the charge is four coke, four ore and two stone, while in others it is two coke, two ore and one stone. By the first method there is just twice as much material in each charge as in the second method. Still another instance is known where the charge was made up of but one coke, one ore and one stone. In order to show clearly how charging the furnace affects the top heat and furnace operation a number of examples used on different furnaces will be given.

In No. 1, the full charge is lowered at once, the stock being put on the big bell in the order of coke, ore and stone. In No. 2, four skips of coke are put on the bell and it is then lowered, then four skips of ore and the bell lowered, and then two skips of stone and the bell lowered. In this method each material is dropped into the furnace separately. In No. 3, the big bell is lowered six times to the round, or after two coke, after one stone, after two ore, after two coke, after one stone and after two ore have been put in. In No. 4, the big bell is lowered four times, once after two coke, once after

DIFFERENT METHODS OF CHARGING THE FURNACE

		Lb.	
1.	4 Coke 4 Ore 2 Stone	3,000 5,700 3,650	Lower big bell once
2.	4 Coke 4 Ore 2 Stone	2,460 5,100 3,030	Lower big bell three times
3.	2 Coke 1 Stone 2 Ore	2,580 2,700 5,400	Lower big bell six times
4.	2 Coke 2 Stone 2 Coke 4 Ore	3,060 3,180 3,060 5,400	Lower big bell four times
5.	2 Ore 1 Stone 2 Coke	5,100 2,880 2,940	Lower big bell twice
6.	2 Coke 2 Ore 1 Stone	5,680 8,000 3,000	Lower big bell once
7.	2 Coke 1 Ore 1 Stone	5,680 4,000 3,000	Lower big bell once
8.	1 Coke 1 Ore 1 Stone	2,840 3,500 3,300	Lower big bell once

two stone, once after two coke and once after four ore. In No. 5, the big bell is lowered only twice, once after two ore, one stone and two coke have been put in and again after two more ore, one stone and two coke have been put in. In No. 6, the big bell is only lowered once, when two coke, two ore and one stone are put in. In No. 7, the big bell is lowered only once after two coke, one ore and one stone have been put in. In No. 8, the big bell is lowered only once, after one coke, one ore and one stone have been put in.

The point to be brought out clearly here is that when the amount of ore and stone is light in proportion to the amount of coke then the top heat is likely to be high, or in other words, when there is a surplus of fuel present.

LETTING THE FURNACE GO DOWN

Smoothest furnace operation is always obtained when the filling is even and regular. It is of vital importance that the stock is not let go down, for this means starting irregular driving. If the furnace is not charged for long intervals of time, this is immediately shown on the top heat chart. The curve will keep on rising until cold stock is put in, when it will show exactly the time recharging began by the fall in the curve. The furnace should be filled as soon as there is room for a charge to be put in. This assures regular driving and heats the charge long before it gets down in the furnace. In addition it keeps the top heat down.

An example of particular interest which illustrates the value of filling the furnace regularly and keeping it full is shown in the following incident. It was in the winter time when about 6 in. of snow was on the ground. The furnace was tested with the gage rod, which registered full. It was tested again some time later, and the rod again registered full. Although there was no evidence of hanging, still after two hours the rod showed the furnace to be full. At the end of four hours suspicion pointed to the gage rod, and it was found that it would go down just so far and then stick.

The furnace had gone down 30 ft. Filling was kept up all night to get it full again. At 4 o'clock in the morning it started to hang. Then the pressure started to rise. Every effort was made to make it take stock,

but the cold stock had come down from above and the furnace went violently cold. At 3:10 in the afternoon the stock came down with a terrific explosion tearing the bottom out of the dust catchers and covering the ground with ore, coke and limestone. It was weeks before it ran smoothly again. This shows the effect of cold stock coming down quickly into the hearth. When the furnace is kept full, the stock is heated gradually all the way down. The top heat chart shows how long the furnace has been let go down, or the interval between filling.

WHITE SMOKE FROM THE STOVE STACKS

White smoke from the stove stacks is an indication of a hot furnace. The top heat may or may not be high at this time, but such a condition is very often accompanied by a high top heat. For instance, a top heat of 870 deg. was shown on a furnace when extremely heavy white smoke could be seen at the stoves and boilers. As the fumes or smoke decreased in volume the top heat went down to 740, then 620, and then to 580.

SLIPS

Slips are shown on the top heat chart by an immediate rise in top heat. The stock having dropped down in the furnace, the loosened charge allows the hot gases to come clear to the top of the furnace. Just as soon as filling starts the cold charges going in have the effect of lowering the temperature. This is seen by the falling step-like top heat curve, which shows a step down when each new charge is dropped in.

SLOW DRIVING

It is natural to expect a rise in the top heat when the furnace drives slow and a fall in the top heat when the furnace drives fast. The explanation is simple, so it will not be discussed. A typical example of extremely high top heat is shown on a heavily limed furnace which only took thirty-eight charges during the day. The top heat was around 875 deg. and all during the day there were explosions on top due to the high heat. The stock was heavily watered and as a radical resort even full skips of water were run into the furnace before the top heat was finally brought under control. This is an example of slow driving.

The same furnace, which normally took forty charges to the shift, showed a top heat of 520 deg. on fast driving lean furnace when forty-five charges were put in. At another time a top heat of 500 deg. was registered when forty-six charges were put in. It might be stated the normal top heat of this furnace was 400 to 500 deg.

As stated before, the position of the fusion zone has a decided influence on the top heat. This same furnace showed a top heat of 600 to 670 deg. when forty-eight charges were put in, but the fusion zone was high. One of the quickest ways to raise the fusion zone is by putting a large extra coke blank or by running in cold air over a considerable length of time.

It must be remembered that furnace conditions are very flexible and the examples cited are the general behavior under certain definite operation. For example, a furnace on lake ores was cold on top and hot in the bottom and took only twenty-two charges, which was extremely slow driving. The top heat registered only 350 deg. The filling report shows the furnace to be hanging all day and twenty extra skips of coke were

put in. Thus it is seen that there are exceptions to the rule.

On the other hand, often ideal examples occur. Such an illustration showed that the top heat curve ran all day long and all night evenly recording 400 deg. top heat. The top heat curve was an even saw-toothed curve all the way around, with no large peaks or any irregularities of any kind. The stove heat was 950 deg. all day, the blast pressure ran smoothly all day long at 9.5 lb., and driving was smooth, quiet, even and regular. These conditions were ideal furnace conditions and therefore as the result an ideal top heat curve was recorded.

OTHER FEATURES AND INDICATIONS OF HIGH TOP HEAT

The stove changes not only affect the stove charts but often, especially when making a radical change in the stove heat, say from 700 to 1,000 deg., the increase in temperature is also noted with a corresponding small increase in top heat.

During a shut-down to change a tuyere, cooler, water block, etc., there is a rise in temperature of the top heat, which is indicated by the rise on the chart during the shut-down interval. This is easily explained as due to the decrease or entire slowing down of the

velocity of the gases. They are not carried off so rapidly and hence are much hotter.

It is interesting to compare the top heat charts of a skip-filled and a hand-filled furnace. The peaks or teeth of the former are regularly larger than the fine, small, band-saw teeth of the hand-filled furnace. A hand-filled furnace is seldom full and the filling is therefore continuous, while with a skip-filled furnace the stack is filled in from twenty to twenty-five minutes and then allowed to drive for about the same interval of time.

Brief mention has previously been made of the influence of extra coke on the top heat. It is naturally to be expected that a rise will be shown in the top heat after a large extra coke blank. A furnace running on lake ores which showed a top heat around 350 deg. showed a top heat of from 650 to 700 deg. after eighty skips of extra coke had been put in. Another instance was seen when the top heat ran around 1,000 deg. when sixty extra coke were put in every day for a week.

The top heat curve falls off to nothing when the furnace is banked. This is gradual and is registered as an even falling curve on the top heat chart.

Pittsburgh, Pa.

Determination of Available Lime in Quicklime and Hydrated Lime

BY ALICE I. WHITSON

FOR most chemical purposes free or uncombined calcium oxide is the valuable constituent of lime, and in practice limes are bought and sold on this basis. Notwithstanding this fact, there is no generally accepted method for obtaining this value, and there has been for some time a demand from various industries for a practical and reliable method.

At the request of the Interdepartmental Conference on Chemical Lime, a series of comparative analyses was made by the Geological Survey, the Bureau of Chemistry and the Bureau of Standards, each using duplicate samples of high-calcium and high-magnesium quick and hydrated limes representing the four types of lime in use. Complete gravimetric analyses were first made for comparison purposes and calcium oxide determinations were then made by the seven methods for the determination of free lime given in detail by R. K. Meade in *Concrete*, vol. 10 (1917), Cement Mili Section, p. 25.

The results obtained by the Scaife method were most promising and further investigation of this method at the Bureau of Standards led to the following modified procedure:

Place 1.4 g. of the carefully prepared and finely ground (passing 100 mesh) lime in a 400-c.c. beaker, add 200 c.c. of hot water, cover, heat carefully and then boil for three minutes.

Cool, wash down cover, add two drops of phenolphthalein and titrate with N hydrochloric acid, adding the acid dropwise as rapidly as possible and stirring vigorously to avoid local excess of acid. When the pink color disappears in streaks, retard the rate of addition of acid somewhat, but continue until the pink color disappears entirely and does not reappear for 1 or 2 seconds. Note the reading and ignore the return of color.

Repeat the experiment, substituting for the 400-c.c. beaker a 1-liter graduated flask carrying a one-hole stopper fitted with a short glass tube drawn out to a point. Cool and add dropwise and with vigorous stirring 5 c.c. less acid than before. Call the number of c.c. used A. Grind up any small lumps with a glass rod flattened at one end, dilute to the mark with freshly boiled distilled water, close the flask with a solid stopper, mix thoroughly for 4 or 5 minutes and let settle for half an hour.

Pipette a 200-c.c. portion, add phenolphthalein, and titrate slowly with 0.5 N hydrochloric acid until the solution remains colorless on standing 1 minute. Call this additional number of c.c. B. Then the percentage of available CaO = $2A + 5B$.

Table I presents determinations which were made by the modified method.

TABLE I. DETERMINATIONS OF AVAILABLE LIME BY MODIFIED SCAIFE METHOD

Sample	Uncombined CaO Present (Calculated From Complete Analysis)	Available Lime Found	
		Operator A	Operator B
Calcium quicklime.....	93.4	93.4	93.4
		93.5	93.3
Calcium hydrate.....	87.3	85.0	85.0
		85.0	84.3
High-magnesium quicklime	58.0	57.9	58.0
		58.0	58.1
High-magnesium hydrate...	50.0	50.3	50.0
		50.0	50.1
MgO and CaO, (0.7 g. each)	49.0	49.3	
		48.8	
CaO (precipitated).....		100.0	

All figures are based on the lime ignited at red heat, as prescribed in A.S.T.M. specifications for hydrated lime¹, and the hydrochloric acid was standardized by means of Bureau of Standards benzoic acid No. 48-a, through a sodium hydroxide solution.

It is apparent that the determinations on duplicate samples by the modified method agree within reasonable limits and closely approximate the calculated values. The modified Scaife method is approved by the Interdepartmental Conference on Chemical Lime, and is now being tested in Government and works laboratories.

Elements of the Superconcentration of Nitric Acid

Application of Distillation Studies of $\text{HNO}_3:\text{H}_2\text{SO}_4:\text{H}_2\text{O}$ Mixtures to the Economical Production of Highly Concentrated Nitric Acid From Weak Acid—Preconcentration by Distillation Should Precede Superconcentration With Sulphuric Acid—Effect of Hydrochloric Acid and Nitrogen Tetroxide

BY ERNST GALLE

IF WE follow the history of the technology of nitric acid, we can differentiate two great periods. In the first, nitric acid was manufactured from Chilean saltpeter; in the second, from atmospheric nitrogen by means of the electric arc or from ammonia. Both periods have this in common, that the acid is not obtained in concentrated form and must first be concentrated or superconcentrated.¹ It is easy to appreciate, therefore, that from early times the study of nitric acid-water mixtures has attracted the interest of the chemist, resulting in the publication of a series of articles whose findings will be briefly summarized in the following.

PROPERTIES OF AQUEOUS NITRIC ACID SOLUTIONS

Dalton found (*Ann. Phil.*, vol. 9, p. 186, vol. 10, pp. 38 and 83) that in the distillation of an acid whose density is less than 1.40 at first a weaker acid comes over, until the constant distilling residue has a density of 1.42; this residue boils at 120 deg. C. According to Mitscherlich it boils at 120 to 121 deg. C.; according to Millon at 125 to 128 deg. C.; according to Smith at 121 deg. C. At ordinary atmospheric pressure, after sufficiently long boiling of nitric acid of any concentration between 70 per cent and 65 per cent, there is finally obtained a residue of constant composition containing 68 per cent HNO_3 , whose boiling point at 735 mm. mercury is 120.5 deg. and whose density is 1.414. If the distillation is carried out at 70 mm. pressure the residue contains 66.7 per cent HNO_3 and boils under this pressure at 65 to 70 deg. C. At 150 mm. the HNO_3 content is 67.6 per cent, at 1,220 mm. 68.6 per cent—i.e., 0.6 per cent higher than at ordinary pressure.

If, by the passage of dry air, one-third, one-half or three-fourths of the acid is evaporated, the residue shows a composition dependent upon the temperature but independent of the composition of the acid used, and contains at 13 deg. C. 64 per cent, at 60 deg. C. 64.5 per cent, at 100 deg. C. 66.2 per cent HNO_3 (Roscoe, *Ann. Phil.*, 203, 1860).

The peculiar discontinuity of the properties of aqueous nitric acid solutions led to the assumption of the presence of various hydrates, which were first reduced by Küster & Koomann² [*Z. anorg. Chem.*, vol. 41, p. 1 (1905)] to $\text{HNO}_3 \cdot 3\text{H}_2\text{O}$ and $\text{HNO}_3 \cdot \text{H}_2\text{O}$ and isolated by Pickering [*J. Chem. Soc.*, vol. 63, p. 436 (1893)]. More complete summaries, which will not be taken up as beyond the scope of this article, are found in Abegg, "Handbuch der anorganischen Chemie," vol. III, part

3, p. 158, and Spiegel, "Der Stickstoff und seine wichtigsten Verbindungen," p. 204.

If the two curves in Fig. 1 are examined, of which the first gives the boiling points of nitric acid solutions of various concentrations and the second the boiling points of sulphuric acid solutions of various concentrations, it can readily be seen that aqueous nitric acid can be separated by simple distillation only to an acid

FIG. 1. BOILING POINTS OF SULPHURIC AND NITRIC ACIDS

The curves in the original article were not copied, but for sulphuric acid the figures of the Manufacturing Chemists' Association were used and for nitric acid those of Creighton and Githens.

of 68 per cent strength, while aqueous sulphuric acid yields an acid of 98.3 per cent strength. Consequently, in order to obtain a highly concentrated nitric acid, two separate phases must be considered:

a concentration to 68 per cent and a superconcentration to 98 per cent, which latter must principally be carried out with other means

than is the case with sulphuric acid. Experiments by Guido Pauling give the results shown in Fig. 2, when distilling acid below 68 per cent strength.

Concerning the distillation of acids stronger than 68 per cent, experiments have yielded the following:

Nitric acid having a density of 1.503, freed from N_2O_4 by blowing warm

air through it, showed boiling points rising from +88 deg. to +121 deg. C., leaving behind at the latter temperature a residue containing 77.1 per cent HNO_3 . The portion boiling between 88 deg. and 93 deg. is strongly colored red; when bleached, this acid has a density of 1.516 and a boiling point of 84.4 to 86.7 deg.; when redistilled it yields an acid of 1.517 density with a boiling point of 84.4 deg. C. (Smith, *Pharm. Centralbl.*, vol. 19, p. 203).

Acid of a density of 1.55 when distilled first yields an acid of 1.62 density (containing N_2O_4), then of 1.53; the residue shows a density of 1.49 (Proust). More lately Creighton and Githens [*J. Franklin Inst.*, vol. 179, p. 161; abstr. in *Z. angew. Chem.*, vol. 2, p. 208

FIG. 2. RELATION BETWEEN BOILING NITRIC ACID SOLUTIONS AND THEIR VAPORS

Translated from *Z. angew. Chem.*, 1921, vol. 34, pp. 168-170, 173-175, by F. C. Zeisberg, Chemical Department, E. I. du Pont de Nemours & Co.

¹There is no English equivalent of the German "Hoehkonzentration," used both as noun and verb. The word "superconcentration" has hence been coined, to be applied when the resulting product, particularly nitric acid, is concentrated to a high degree (above 90 per cent in the case of nitric acid). F.C.Z.

²Undoubtedly an error for "Kremann." F.C.Z.

(1916)] have determined the boiling points and vapor pressures of aqueous nitric acid solutions by the dynamic method. From the locations of the maxima of the boiling point curves the variation of the composition of the mixtures of maximum boiling point with the pressure is established.

Interesting results were also obtained by Konrad Schaefer [*Z. angew. Chem.*, vol. 2, p. 56 (1916)] from the absorption spectra of gaseous nitric acid. The NO_2 group exists in two constitutionally different modifications: a selective absorbing form in inorganic nitrates and dilute aqueous nitric acid, and an end absorbing form in alkyl nitrates, in concentrated nitric acid solutions and also in gaseous nitric acid.

DEVELOPMENT OF NITRIC ACID TECHNOLOGY

Let us now examine the period during which nitric acid was made from Chilean saltpeter and sulphuric acid. In his "Handbook of Sulphuric Acid Manufacture" Lunge pictures the development of this industry from its first beginning up to the present. From the statements therein we see the efforts made to recover as high a concentration as possible of nitric acid, through changes in the apparatus and by means of various devices. By means of the processes of Guttman and the Chemische Fabrik, Griesheim (Ger. Pat. 59,099), Uebel's three retort system (Ger. Pat. 106,962) and Valentiner's vacuum distillation process (Ger. Pat. 63,207) this aim was achieved.

By this time the processes for making nitric acid from atmospheric nitrogen were already figuring in the technique. In their book "The Technical Utilization of Atmospheric Nitrogen" Donath and Frenzel give a collected review of the work in this field. "The Oxidation of Ammonia to Nitric Acid" has been treated by Donath and Indra in a monograph whose basic contents have been included by Lunge in the fourth edition of his handbook of the sulphuric acid industry. From all these processes only weak nitric acid results, which in the best cases contains 50 per cent HNO_3 . If this is not directly worked up into ammonium, potassium, sodium or barium nitrate, but is destined for the explosives industry, then a further concentration is unconditionally necessary.

THE IMPROVED PAULING CONCENTRATION PROCESS

The process of Pauling, already used successfully on the large scale before the war, has, after many improvements by Dr. A. Hoenig, which among others included raising the capacity from a steam consumption of 1,500 kg. per 24 hours to 19,000 kg., proved very good. The original Pauling process showed a great many disadvantages. Above all, in case of stoppage from mud, it was impossible to remove the Steuler filling material. It was necessary to wash for a long time with water to set the tower in order again. In washing, acid losses naturally occur, while on the other hand both the lining and the packing are likely to crack from local overheating. In order to avoid these disadvantages the manhole 1, as shown in Fig. 3, was devised by Dr. Hoenig.

The Steuler packing, of the size of a man's fist, necessitated a low rate of acid feed and a correspondingly low steam consumption. By filling the tower with Raschig rings the water evaporating capacity was increased twelvefold. Moreover, stoppages from mud were observed much more infrequently. The rings, also, have proved very resistant; after 1,000 hours'

operation the decrease in weight was hardly worth mentioning (0.21 per cent).

The final form of Dr. Hoenig's improved Pauling tower is best described by means of the diagrammatic sketch in Fig. 3. This consists of a column A, of about 8 m. height, of cast-iron sections. The lower section (base section *a*) carried the manhole 1, the steam jet *F*, and the exit pipe 2, for the denitrated, dilute sulphuric acid. Between the bottom section *a* and the second section *b* a silicon iron grating *G* is inserted, which carries the packing (Raschig rings). The top section *g* is not packed. It contains the acid distributor *H*, and carries the gas exit pipe 3, which leads to the condenser, the three inlet pipes for dilute nitric acid 4, concentrated sulphuric acid 5 and waste acid 6, as well as a thermometer 7. The column is lined with acid-resisting masonry.

The condenser *B* is a silicon iron coil cooled by a water spray. The 49 deg. acid condensing here runs off through the pipe 8 to earthenware pots, from which the acid can be filled into traveling pots or carboys. In

addition, the condenser is connected, through pipe 9, with a stoneware exhaustor, which blows the gases uncondensed in *B* into absorption towers, in which the last portions of nitrous oxides are absorbed. The weak acid resulting therefrom is returned to the process. The weak denitrated acid running off at a strength of 57 deg. Bé. enters the cooler *D* and from here goes to the sulphuric acid concentrating plant.

At *E* is the acid distribution. From reservoirs set higher the dilute nitric acid flows through the glass vessels 11 and 12; the concentrated sulphuric acid and the waste acid flow to the tower. The amount of acid added can be roughly regulated by varying the cross-section of the siphon, the finer regulation being obtained by using the adjustable level 11. For handling all the

FIG. 3. IMPROVED PAULING PROCESS.

acid, silicon iron pumps (Patscher construction) and pumps of acid-proof castings with chromium steel shafts made by Eichler in Wesseling have proved excellent. Before operating, the tower must first be heated to a certain high temperature. To do this, concentrated 66 deg. sulphuric acid is allowed to run slowly into the tower through pipe 5 for about 48 hours. At the same time, steam is admitted carefully through *F* with a pressure of two atmospheres. Both the acid and the steam are gradually increased until after 48 hours the thermometer 7 reads 130 deg. Then, through 4, dilute 30 deg. Bé. nitric acid is allowed to run in and the sulphuric acid and the steam are so regulated that a nitric acid of 49 deg. flows off through 8 and the residual sulphuric acid is free from nitric acid. With normal operation the thermometer 7 stands at about 112 deg. C., thermometer 13 at about 167 deg. C., and the residual sulphuric acid has a strength of about 57 deg. Bé. (73 per cent H_2SO_4).

According to Pauling's original statements 5 parts of concentrated sulphuric acid should be used to concentrate 1 part of nitric acid. As an experiment, waste acid (75 per cent H_2SO_4 , 12 per cent HNO_3 , 13 per cent H_2O) was allowed to flow in through 6; it developed that the tower would completely denitrate this acid, and in addition that concentrated sulphuric acid equivalent to the sulphuric acid content of the waste acid could be saved. The partial reduction of nitric acid to nitrous acid brought about by the nitro-body content of the waste acid was neutralized by increasing the size of the condenser. Let us now examine in the following table of operating results, and the data calculated therefrom, the nitric acid-sulphuric acid ratios on the one hand and the water-sulphuric acid ratios on the other, obtained with the tower operating full capacity (10,000 kg. 99 per cent HNO_3 in 24 hours) and with different strengths of weak nitric acid fed to the tower.

The operation of the tower for 24 hours then gives:

	H_2SO_4 , kg.	HNO_3 , kg.	H_2O , kg.
H_2SO_4 (66 deg.)	43,000		6,970
HNO_3 (33 deg.)		11,280	13,620
Steam			1,390
	43,000	11,280	21,980

SULPHURIC ACID CONSUMPTION INCREASED WITH DILUTE NITRIC ACID

If waste acid is added, the addition of concentrated sulphuric acid is reduced correspondingly, without, however, causing any change in the remaining ratios. Much more sulphuric acid is, however, necessary with dilute nitric acid. Care must hence be taken, by adding various stronger acids, not to allow the concentration to drop below 30 deg. On the contrary, if the acid is stronger, then not only is the production of highly concentrated acid in unit time greater but the sulphuric acid consumption drops appreciably. (See Table I.)

Now, there was not only pure atmospheric nitric acid available for superconcentration, but also various dilute nitric acids containing hydrochloric acid. With these latter the sulphuric acid consumption increases considerably, as compared with the consumption for pure acids of like concentration; the explanation for this

TABLE I. OPERATING RESULTS WITH DIFFERENT STRENGTHS OF WEAK NITRIC ACID

Strength of Weak Nitric Deg. Bé.	Per Cent	$\text{HNO}_3 : \text{H}_2\text{SO}_4$	$\text{H}_2\text{O} : \text{H}_2\text{SO}_4$	Remarks

30		0.143	0.250	Weak acid with 2 per cent HCl

is given in experiments to be described later. Above, the corresponding figures obtained in actual operation are given.

BEHAVIOR OF NITRIC ACID-SULPHURIC ACID MIXTURES

Experience shows, therefore, that in superconcentrating very dilute acids or acids containing hydrochloric acid the sulphuric acid consumption increases, with an appreciable decrease in the production. The following experiments were hence carried out to study the causes of this phenomenon, in order, so far as possible, to avoid them. Very few references are available in the literature with respect to the behavior of nitric acid-sulphuric acid mixtures. The only known work is the study of A. Saposchnikow, appearing in the *J. Russ. Phys. Chem. Soc.*, and mentioned in the *Chem. Zen-*

tralbl. (1904, p. 395; 1905, pp. 381, 1152)¹. Saposchnikow investigated the partial pressure of nitric acid mixed with increasing amounts of sulphuric acid, the composition of the vapor carried out of these mixtures by the air stream at 25 deg. C., the vapor density of these mixtures and their electrical conductivity. The picture of the reaction, given in the form of curves, is veiled by the nitrogen oxide content of the nitric acid used. Further, he found the vapor pressure of an acid of 1.478 sp.gr. to be much lower than that of an acid of 1.52 sp.gr.—viz., 16.64 mm. By the addition of H_2SO_4 , it increases noticeably, reaching a maximum in mixtures with 35 per cent H_2SO_4 . Numerous systematic experiments on the nitrating action of nitric acid-sulphuric acid mixtures on cellulose are mentioned. Besides, he concludes from his experiments on the vapor pressures at 25 deg. C. that the water contained in concentrated nitric acid (42 deg. Bé.) is completely removed by the sulphuric acid, which circumstance explains the applicability of such mixtures to the manufacture of nitrocellulose. From the partial pressure curves it is to be seen that very small amounts of water reduce the partial pressure of nitric acid very considerably, which explains why even the strongest nitric acid, without sulphuric acid, is not suitable for the manufacture of nitrocellulose. In further experiments he studied the nitrating action of sulphuric acid mixtures with dilute nitric acid and found that the water-abstracting sulphuric acid increased the number of free molecules of nitric acid.

More lately Creighton and Githens (*J. Frank. Inst.*, vol. 180, p. 703) investigated the influence of sulphuric acid on aqueous nitric acid at atmospheric and reduced pressures, and found that at 760 mm. nitric acid of maximum boiling point contains 68.18 per cent HNO_3 , without sulphuric acid, 64.5 per cent in the presence of 10 per cent H_2SO_4 , and 59.2 per cent in the presence of 20 per cent H_2SO_4 .

Konrad Schaefer (*Z. angew. Chem.*, 1917, p. 56) made optical experiments in this domain and found that dehydration of nitric acid results in a constitutional change in the NO_2 group. Very likely those nitric acid molecules which contain the end absorbing form of NO_2 group largely, or perhaps wholly, react during nitration. These, to my knowledge, are the only researches in this field.

DISTILLATION PHENOMENA WITH WEAK NITRIC ACID

In the following are given the experiments carried out by the author on the superconcentration of nitric acid and their results. As raw material for the following first series of experiments a nitric acid of 25 deg. Bé. was used, obtained by the oxidation of ammonia by the Ostwald process. Analysis showed: Sp.gr. 1.210, HNO_3 33.48 per cent, HNO_2 0.14 per cent.

Of this acid 500 c.c. (corresponding to 167.4 g. monohydrate) was distilled in a distilling flask fitted with a Liebig condenser. Between 102 and 106 deg. 256 c.c. passed over; in the flask 244 c.c. remained. The distillate tested 2.1 deg. Bé. and analyzed, sp.gr. 1.015, HNO_3 2.90 per cent, HNO_2 0.29 per cent. The residue tested 41.2 deg. Bé. and analyzed, sp.gr. 1.400, HNO_3 65.56 per cent, HNO_2 0.00 per cent.

¹Galle is evidently unfamiliar with the work of Pascal. See Pascal, *Compt. rend.*, vol. 165, pp. 589-91 (1917), and C. de la Condamine, *Ind. Chim.*, No. 54, pp. 153-5, 187-9 (1918), for partial pressures of mixed acid solutions at boiling temperatures, and their boiling points; Pascal and Garnier, *Bull. Soc. Chim.*, vol. 27, p. 18 (1920) for specific heats of mixed acid solutions and *Bull. Soc. Chim.*, vol. 25, p. 145 (1919), for sp.gr. of mixed acid solutions at various temperatures.

In order to study the relations more closely another 500 c.c. was distilled and the distillate was caught in 25 c.c. lots and titrated with N/2 NaOH and methyl orange. From a series of experiments, which agreed well among themselves, the average figures shown in Table II were obtained.

Besides, it was observed that already at 90 deg. vapors of NO_2 appeared which dissolved partially, with the development of a blue color, in the first portions of the distillate and partially escaped into the air. A peculiar smell was also observed, reminiscent of ozone,

TABLE II. DISTILLATION OF 500 C.C., 25 DEG. BÉ. NITRIC ACID

but which could not be chemically proved to be this substance. Graphically expressed, the strength of the resulting acid is given in Fig. 4.

PRECONCENTRATION OF WEAK NITRIC ACID

Next, an attempt was made to see whether it was possible to obtain a distillate wholly free from HNO_2 , in order to investigate the possibility of preconcentrating the weak acid commercially and thus to avoid the irksome necessity of returning the dilute 3 per cent distillate to the nitric acid absorption towers of the ammonia oxidation plant. After many experiments an apparatus of the following design (see Fig. 5) was finally constructed by a glass blower, and insulated with asbestos paper. The flask A had a volume of about 1 liter; the column B, filled with glass beads, was 40 cm. long and 4 cm. in diameter, and contained at the top a thermometer

well b, which was fused in. In order to facilitate charging with weak acid, the opening C was provided.

Again, 500 c.c. of dilute nitric acid was subjected to distillation. The thermometer rose to 99 deg. C. and 225 c.c. distillate passed over. Then the distillation began to lag. By adding a second burner it became more lively, but the temperature also rose. Table III again gives the average of a series of distillations.

The residue of 250 c.c. showed a sp.gr. of 1.40 and contained 64.14 per cent HNO_3 . From these experiments it is clearly evident that it is possible with suitable apparatus to preconcentrate nitric acid to about 65 per cent without the addition of a water-binding material; a further concentration is, of course, out of the question.

SUPERCONCENTRATION OF PRECONCENTRATED ACID

Experiments were then made to superconcentrate the acid of 41 to 42 deg. Bé. thus obtained, by the addition of sulphuric acid. An acid of sp.gr. 1.410, containing 67.10 per cent HNO_3 and 0.02 N_2O_4 , served as a

TABLE IV. DISTILLATION OF HNO_3 (1.410) + H_2SO_4 (1.84)

$\text{HNO}_3 : \text{H}_2\text{SO}_4$	$\text{H}_2\text{O} : \text{H}_2\text{SO}_4$	Boiling Point, Deg. C.	Per Cent HNO_3 in Dist.
5 00	2 40	118.8	74 66
2 42	1 20	117 6	79 72
1 61	0 81	113 8	84 55

0 50	0 25	93 0	96 72
0 40	0 20	88 6	96 74

starting point. This was mixed in the distilling flask with sulphuric acid of 66 deg. and distilled. From a series of experiments in which 25 c.c. portions of the distillate were again collected, the results shown in Table IV were obtained.

From this it is evident that it is possible, by the addition of concentrated sulphuric acid, to obtain highly concentrated nitric acid from an acid of 1.41 sp.gr. An acid of 96.8 per cent HNO_3 (on the large scale, continuously, 99 per cent HNO_3) is obtained in the laboratory even when the water:sulphuric acid ratio is 0.5—i.e., when the water contained in the 1.41 acid has the ratio 1:2 to the sulphuric acid monohydrate. A further addition of sulphuric acid, it is true, raises the vapor pressure of the nitric acid-sulphuric acid-water mixture, and as a result thereof lowers the boiling point,

but this is without significance in the industrial process. If hydrochloric acid is added to the nitric acid (2 per cent of the monohydrate content), a raising of the boiling point to 113 deg. C. resulted with the $\text{H}_2\text{O}:\text{H}_2\text{SO}_4 = 1:2$ ratio, and an acid of 90.18 per cent HNO_3 distilled over, which, however, contained 0.41 per cent NOCl . This result corroborates the operating fact that a larger amount of sulphuric acid is necessary to superconcentrate nitric acid which contains hydrochloric acid. The hydrochloric acid content raises the boiling point, the vapor pressure is lowered as a result of the

FIG. 5. PRECONCENTRATION APPARATUS

formation of nitrosyl chloride, and this latter must be broken down by an excess of sulphuric acid in order to make possible a normal operation.

SUPERCONCENTRATION WITHOUT PRECONCENTRATION

Next, experiments were carried out to learn how the dilute acid direct from the oxidation process, without any preconcentration, behaved when subjected direct to superconcentration with sulphuric acid. First, an acid obtained from the oxidation of ammonia (by the Ost-

way. In Table VI the average figures from a series of experiments are given.

If the figures given in Tables IV, V and VI are now plotted on co-ordinate paper, the results shown in Fig. 6 are obtained. The abscissas represent the $\text{H}_2\text{O}:\text{H}_2\text{SO}_4$ ratio and the ordinates of the upper set of curves boiling points. The ordinates of the lower set of curves represent strength of distillate.

DIRECT SUPERCONCENTRATION OF WEAK ACID UNECONOMICAL

From these diagrams it is evident that the more concentrated the nitric acid is which is to be distilled the less sulphuric acid is necessary to superconcentrate it. With increased addition of sulphuric acid the vapor pressure is raised and the boiling point approaches that of pure nitric acid. With the decrease in boiling point the concentration of the distillate simultaneously increases. The use of nitric acid containing hydrochloric acid is, so far as possible, to be avoided in the concentrating operation.

On the manufacturing scale it is hence evident that the use of an acid weaker than 40 deg. Bé. is without question to be avoided. Care must be taken to preconcentrate to 40 deg. and then first to employ the resulting acid for superconcentration. An example will be given: If acid of 30 deg. is subjected to superconcentration, then roughly five times the weight of the nitric acid monohydrate of sulphuric acid will be necessary—viz., in 24 hours 10,000 kg. of HNO_3 (99 per cent) requires 50,000 kg. of H_2SO_4 (66 deg.). If this 30 deg. acid is replaced, through preconcentration, with acid of 40 to 42 deg. Bé., then for the same daily production of nitric acid 20,000 kg. of sulphuric acid suffices, 40 per cent of that necessary in the first case. No cog-

nizance has been taken of the fact, either, that as a result of the discharge of stronger acids the capacity of the tower is appreciably increased in the second case. Since in practice, however, the capacity of a concentrating plant is usually dependent upon that of the sulphuric acid concentrating apparatus, it is self-evident that, presupposing the necessary spares for superconcentration, the output of a superconcentration plant can be about trebled by preconcentration.

AVOIDING LOSSES DUE TO NITROGEN TETROXIDE

Since it is often the case that weak nitric acid from denitrating operations is sent to the superconcentrating plant, or, to save sulphuric acid, so-called waste acids

are run into the concentrating tower, the behavior of the nitrogen tetroxide contained in these acids was investigated. First, a waste acid from a nitro-cotton factory, of the following composition, was distilled: Sp.gr. 1.710, H_2SO_4 70.00 per cent, HNO_3 6.74 per cent, N_2O_4 2.86 per cent, H_2O 20.40 per cent; color yellow green. There first condensed a yellow green liquid, which later became underlain with a brown colored layer; some uncondensed nitrogen tetroxide escaped. Because of

FIG. 6. EFFECT OF $\text{H}_2\text{O}:\text{H}_2\text{SO}_4$ RATIO ON CONCENTRATION OF NITRIC ACID

the great volatility of the condensed substances (on sucking them into a pipette they vaporized), these could be regarded as nitrous acid (Fritsche, *J. prakt. Chem.*, vol. 19, p. 179) and nitrogen tetroxide (Dulong, *Ann. chem. phys.*, vol. 2, p. 317).

When the distillate was absorbed in potassium hydroxide solution, crystals of potassium nitrate separated in the course of the distillation, while the mother liquor contained potassium nitrite. If nitric acid of high N_2O_4 content is mixed with sulphuric acid and distilled, then only 50 per cent of the N_2O_4 given off is found in the distillate as such. The other half has been oxidized to nitric acid. On this basis half the N_2O_4 contained in highly concentrated nitric acid may be reckoned as nitric acid, since in nitrations it reacts as nitric acid.

In working up nitric acids rich in N_2O_4 it is well, therefore, also to provide an alkaline absorption following the water absorption, to avoid nitric acid losses; the nitrite solution obtained is worked up into nitrate.

SUMMARY

Summarizing this work, the following rules for the superconcentration of nitric acid are indicated:

1. The weak nitric acid must be preconcentrated, without the addition of sulphuric acid, to 42 deg. Bé.
2. The 42 deg. nitric acid is superconcentrated with sulphuric acid, using twice as much sulphuric acid as the water contained in the nitric acid.
3. If the dilute nitric acid contains HCl , then the

H₂SO₄ necessary for superconcentration is increased, with 42 deg. Bé. acid as well as with weaker ones.

4. The N₂O₄ contained in the weak nitric acid is converted into nitric acid to the extent of 50 per cent, in the superconcentration of nitric acids containing it. Equally, 50 per cent of the nitrogen tetroxide in highly concentrated nitric acid reacts as nitric acid in the mixed acid made therefrom.

Progressive and Compartment Dry Kilns for Timber Compared*

The dry kiln becomes yearly of increasing importance to technically-controlled processes, and the findings in each particular instance of operation are valuable for application to conditions in other lines. This may be true of recent work with kilns used in drying lumber.

All lumber dry kilns now on the market are either progressive or compartment kilns. In the progressive type the drying conditions increase in severity from one end of the kiln to the other, the material being moved into severer conditions as it dries. In the compartment type the same temperature and humidity prevail throughout the kiln at any one time, beginning with mild conditions and increasing in severity as the material becomes dry.

The progressive type of kiln requires less skill in the operator. It consumes less heat per pound of water evaporated from the wood, but the saving of steam possible should not be considered so important as the question of ability to perform the work required with the best results. The progressive kiln reaches its greatest heat efficiency in drying from the green state and is most useful in circumstances which permit of

its being supplied continuously with green lumber of one thickness and class. It is, however, impracticable with this type of kiln to give individual attention to special loads of lumber.

The compartment type of kiln is more flexible and affords greater control over the drying conditions, permitting less change in temperature, humidity and circulation in the kiln with variations in the wind and weather. It is better adapted to meet the varying requirements of different kinds of material and is most useful where exact and careful drying is required.

A Convenient Humidity Table for the Wet and Dry Bulb Thermometer

Users of wet and dry bulb thermometers will find the following table, compiled at the Forest Products Laboratory, Madison, Wis., very useful for quickly determining relative humidity values from wet and dry bulb thermometer readings. To use the table, read the temperatures and subtract the wet bulb readings from the dry. Locate the vertical column of figures headed by the appropriate difference between wet and dry bulb readings, and the horizontal row of figures beginning at the extreme left with the observed dry bulb reading. The figure marking the intersection of these rows is the relative humidity value expressed in per cent.

Take the following as an example: wet bulb temperature, 132 deg. F.; dry bulb temperature, 140 deg.; difference, 8 deg. The figure marking the intersection of the vertical column for 8 deg. difference with the horizontal row beginning with 140 at the extreme left is 79, which is the correct relative humidity for the given thermometer readings.

Hammer-Welding Plant of the Blaw-Knox Co.

New Plant and Process for Making Large Seamless Tanks and Sheet-Steel Vessels
Described by Tracing the Course of an 8-Ft. Boiler Shell
of $\frac{7}{8}$ -In. Plate Through Its Manufacture

BY ERNEST EDGAR THUM

IN A FOREGOING article¹, entitled "Welding, Particularly Hammer Welding," a general survey was given of the various methods now in common use for joining metals into a continuous substance. It was noted that all the new methods extended the use of welding to joints which would not be attempted by the blacksmith.

Hammer welding is an adaption of the methods of the smith to quantity production and to pieces so large that they are entirely unmanageable without adequate mechanical handling. Consideration of the fundamentals indicated that a mechanical welding operation, simulating hand-forging, must heat the pieces rapidly to the correct temperature without oxidation, and quickly hammer the hot metal together, continuing the work to recalescence. Transfer of tools or heated metal must be very rapid. The work must be firmly held. Finally the completed article must be bodily put into an annealing furnace, to relieve internal strains and refine the grain.

Such operations must remove as many as possible of those empirical conditions which are so difficult to control in handwork and which make it remarkable that so many welds are good, not that a few are very bad.

While any forge shop which has applied the principles of modern metallurgical control to welding under the steam or drop hammer may justly claim to practice hammer welding, and while a brief description of the Navy's excellent plant for making anchor chain was included in the former article, it would be better at this time to restrict the term to the welding of long seams in plate work. The advantages of "seamless" containers for volatile gases and fluids are obvious. Equally apparent must be the utility of welded vessels which must withstand wide variations in temperature and pressure. Welded pipe should be an attractive material for lines offering a minimum frictional resistance to flow of liquid.

Perhaps half a dozen concerns in the United States are now equipped to turn out this material. However, information regarding their equipment and the process has been closely held. Considerable credit, therefore, is due to the officials of the Blaw-Knox Co. and the National Tube Co. for their broad-mindedness in opening their plants for inspection.

What follows is a description of the operating technique of the Blaw-Knox Co. Thanks are due to Messrs. Lehman and Leitelt, vice-president and engineer respectively of that concern, for their helpful co-operation.

BLAW-KNOX PLANT

Briefly, the method for hammer-welding seams in use in the Blaw-Knox Co. is as follows: The various plates, bent or pressed to shape, are assembled with lap joints, and stitched together here and there by a short torch

weld on the edge. The assembly is then placed on a carriage, joint up. A pair of gas flames are held one above the seam and the other directly below. When that region has been brought to a proper heat, the upper and lower torches are quickly replaced by an air hammer and anvil respectively, and the hot spot welded and worked down flat. This cycle is repeated until the seam is welded continuously from end to end. When all the seams are finished, the whole article is annealed; all fixtures applied, and if it is a pressure vessel, it is subjected to hydraulic test.

A plant for negotiating such heavy work naturally has many machine tools and handling devices for storing, shaping, assembling and testing. While interesting, such equipment can hardly be regarded as a part of the welding machinery, and it will be passed with brief mention.

Material is stored at one end. The yard is covered by a 70-ft. span crane of 10-ton capacity. The main shop itself is divided into two aisles, one 70 ft. wide and the other 40 ft. Most of the latter is occupied by the welding machinery, but some is partitioned off for a power house and tool room. In this space are located a motor generator set and switchboard, an air compressor, a high-pressure pump and accumulator for the hydraulic system and a repair shop holding a carefully selected group of machine tools.

Plates measuring more than 1-in. thick are not welded without scarfing, and a modern edge planer with a 20-ft. throat is installed for this purpose. Near by is a very powerful bending roll. It is four-roll set with ability to bend cold plates 20 ft. wide by $\frac{3}{4}$ in. thick, and hot plates $1\frac{1}{2}$ in. thick. These rolls are driven by a 100-hp. electric motor. The center roll of the lower three is supported by hydraulic rams so as to give the proper "squeeze" to the plates in bending. This machine is not only used in forming plates prior to welding but also for re-rolling afterward in order to give a true cylindrical shape to circular work, especially at the seam. For this purpose the end housing is hinged to the foundation, so that an open-ended shell can be slipped under the top roll.

Dished ends, flanged plates and domes are cut to correct shape and pressed, either hot or cold, in another department, well equipped with heating furnaces, flanging rolls and hydraulic presses for this kind of work. Such operations are a common feature of all boiler work, and no special notice need be given them here.

WELDING OPERATION

An operation may perhaps best be described by tracing the course of a boiler shell, say 8 ft. in diameter by 15 ft. long.

A square plate of appropriate size is selected, and the

¹CHEM. & MET. ENG., vol. 25, No. 12, Sept. 21, 1921, p. 553.

edges brushed vigorously with a wire brush to remove any dirt or loose rust. (It is not necessary to have the metal bright before welding, since some oxide is reduced during heating, and the rest melted or fluxed. It is largely ejected during the first hammer blows, but extreme care is necessary to eliminate it substantially from the finished joint.) The plate is then rolled into a cylindrical tube of correct diameter, and so that the edges overlap a distance about the thickness of the plate. On completion of this cold work, the end roll housing drops, and the plate is removed by one of the 10-ton overhead cranes commanding the building.

It is apparent that an exact closure at a long seam made in the rolls is impossible, owing to the fact that there will be a narrow strip of straight, unbent plate along each edge. The plates therefore lap over each other in a blunt angle. Such a seam may often be welded immediately, especially if the bent plate is stiff enough so that there is little tendency for the two edges to spring apart when they are hammered. Shorter seams, heads and smaller fixtures are attached by screw clamps,

FIG. 1. CARRIAGE FOR HANDLING WORK

and "tacked" on by a workman with an oxyacetylene flame. He builds up short fillet welds at intervals of 3 or 4 ft. Then the joint is ready for the welder.

As noted above, in welding work as bulky and heavy as this, it is necessary to bring the fire to the work rather than *vice versa*. This does not obviate the necessity of closely controlled manipulation of the work, however. Blaw-Knox engineers have therefore designed several different carriages for this purpose, one of the simple ones being shown in Fig. 1. There have been electrical controllers installed on the pulpit at the left whereby the carriage is moved bodily forward or back, the cradle may be lifted, or moved to either side; and finally the rollers cradling the work may be rotated without changing their position in space. Thus the operator has three motions of translation and one of rotation at his command, which allows him quickly and surely to adjust the work so that it may rest at exactly the proper angle on the anvil and a blow may be struck in exactly the proper direction.

As may be seen from Figs. 1 and 2, the heating and hammering machine consists essentially of two pivoted arms carrying burners, another with an anvil; a fourth may carry the air hammer, although in the views shown it is held by a jib crane. With the pipe

FIG. 2. HEATING AND HAMMERING MACHINE

properly placed on the carriage, the two burners are swung into position, one just above and one just below the spot where welding is to begin. Fig. 3 is a sketch of these burners, which consists of a box where the gas and air is properly mixed, and a firebrick tuyere, luted in place with refractory clay. The two heavy pipes carrying gas and air serve as supporting arms. In place, the foreman signals an assistant at the rear end of the machine, the gas valve is opened, and the fuel ignited by a small pilot flame. Almost immediately the air valve is opened, quickly reaching the correct amount, when the flame "pops" back to the tuyere, burning in a short, non-luminous roaring flame, completely filling the space between burner and plate, and flaring out along the steel for 6 in. or more on all sides (Fig. 1).

About five minutes is required to reach a welding heat on a 12-in. seam in $\frac{3}{8}$ -in. plate. Temperatures here might readily and advantageously be read by optical pyrometer. Fine sand or borax may be used as a flux,

FIG. 3. SKETCH OF BURNER, WITH BRICK TUYERE IN PLACE

but if the flame is held with a slight deficiency of air, little trouble from slag or oxide is to be expected in low-carbon metal. As the welding heat is approached, molten slag will drip from the metal—in fact the plate itself will be slightly fused at projecting corners. The burners, which are nicely pivoted and balanced, are then swung to one side, the gas and air turned off, and their place immediately taken by the anvil or "horn"

beneath and the hammer above. Inspection of Figs. 1 and 2 will show that both of these fixtures are held on very stout, stiff arms, properly pivoted and actuated by air cylinders so that they can be jammed into place with great dispatch and accuracy. It is necessary that the anvil reach its exact position in bearing over the whole hot spot, especially when welding around blunt corners, else the hammer will merely beat the metal out of shape without effecting a weld. It is understood of course that corner work requires special anvils—the anvil used is in all cases shaped to the contour of the inner surface of the object.

First light blows of the hammer are directed at the corner of the sheet, gradually working across the weld; ejecting any molten material in a sheet of white hot sparks. High-speed blows at full air pressure are continued until the temperature has fallen to a faint red, when the force of the blow is lightened, but continued down through the recalcrescence temperature to a

FIG. 4. DEPHLEGMATOR MADE BY HAMMER WELDING

black heat. The hammer itself is swung so it is moved back and forth by the foreman during this operation; the pipe meanwhile resting solidly on the horn, inertia in the hammer cylinder and arm absorbing the reaction from the blow. Air at 100-lb. per sq.in. is the motive power; the cylinder is 5 in. in diameter, the stroke is 11 in., and a blow is struck 160 times per minute.

About half the length heated is welded in this operation, but in thick plate the region must be reheated and hammered twice more before the combined sheets are worked down to the thickness of the rest of the shell. This produces a lap joint which is at least 3 in. long in any sheet thicker than $\frac{3}{8}$ in. Flux is more liberally used in the second and third heatings. When this spot is finally joined to the foreman's satisfaction, the carriage is shifted and the same cycle of operations repeated on the continuation of the seam.

Thus a cylinder is welded from end to end. As a final operation, it is replaced in the bending rolls, they are adjusted to give the exact curvature required, and the seam rolled back and forth several times to bring this portion to correct shape.

If one end is to be closed, as in Fig. 4, the dished and flanged end sheet² is tacked in correct position by

five or six short fillet welds, the work then placed on the carriage so that the burner and anvil arms reach into the pipe through the open end. One portion of a circular seam is then welded in the regular way; the pipe rotated on its cradle and a diametrically opposite portion finished. Intervening sections are then closed and welded. Large stills such as shown in Fig. 5 can be made, the bottom entirely solid, and the top having a manway not less than 18 in. in diameter, the minimum opening necessary for burner and anvil. Small openings and fixtures such as brackets are often welded in place by an oxyacetylene flame.

FUEL GAS

Water gas is used for the burners at the Blaw-Knox plant. Other gases have been tried elsewhere, but often with indifferent success. While water gas (approximately 46 per cent H₂ and 43 per cent CO) produces a relatively low amount of heat on perfect combustion, it requires but a small amount of air with a corresponding small proportion of nitrogen and consequently gives a very hot flame, as shown in Table I.³

TABLE I. CHARACTERISTICS OF GASEOUS FUELS

Gas	Calorific Power Calories per Cu.M.	Volumes of Air for Combustion	Temperature of Flame, Deg. C.
Natural gas (Pittsburgh).....	8,423	9 35	1,852
Oil gas.....	7,350	7 74	1,915
Coal gas (illuminating).....	5,550	5 79	1,896
Coke-oven gas.....	5,159	5 36	1,892
Carburetted water gas.....	5,008	5 02	1,914
Water gas.....	2 590	2 24	1,924
Ordinary producer gas.....	1,300	1 13	1,555

The small amount of air required for combustion is of greater advantage in another way—it is much easier to get a quick and intimate mixture of gas with, say, two volumes of air than with nine or ten volumes, as would be required for natural gas. Unless the gases are correctly mixed, certain portions of the flame would have a great excess of oxygen, with fatal results to a welded joint. In fact, one of the chief excellences of a

FIG. 5. SEAMLESS STILL FOR CRACKING GASOLINE

smith's fire is the fact that his thick bed of incandescent charcoal effectually prevents the passage of any air until its oxygen has combined at least to carbon dioxide.

Gas is generated in two units built by the United Gas Improvement Co. of Philadelphia, using coke as a fuel. It is not necessary to devote space for an exposition of

²Flanging is arranged so that the ends fit over the sides; heating and hammering operations are then conducted so as to close the flange in to correct diameter, avoiding any expansion of the shell.

³From Richards' "Metallurgical Calculations," vol. 1, p. 190.

the gas manufacture. In practice, the producer is run about one minute on air blast, heating the coke, and wasting the products of combustion. Then a series of valves are changed, requiring about fifteen seconds, and steam is blown through the hot column of fuel, decomposing it into H_2 and CO , the fuel gas. In about three minutes the coke has been so cooled by the reaction that another heating period is necessary. Fig. 6 shows a plan of a typical water-gas generating plant, which corresponds closely to the layout at Blaw-Knox, except that the "blow-up" gases are wasted rather than passing through waste-heat boilers as shown, steam being available elsewhere.

Coarse dust is removed by passing the gas through a water-sealed cyclone dust catcher, and then scrubbed

FIG. 6. WATER GAS GENERATING PLANT

free of finer particles and cooled in a column filled with trays over which water is sprayed. A final purifier filled with wood shavings and rusty iron turnings removes any sulphur compounds. A gas holder of 30,000-cu. ft. capacity acts as a reservoir, from which gas is drawn by an impeller blower, and delivered through a 12-in. main at 1.5-lb. pressure, controlled automatically. Air for combustion is also pumped through a 12-in. main by a similar Roots blower, at 1.5 lb. per sq.in.

After a pipe or tank—in fact any pressure vessel or article to work under anything greater than nominal load—has been completely welded, it is heat-treated. An annealing furnace (Fig. 7) large enough to receive work 6 x 9 ft. in size and 20 ft. long was furnished by Tate, Jones & Co., Inc., for this purpose. It is equipped with ten main and ten auxiliary burners, arranged for either oil or natural gas. Variation in temperature in the furnace is held to within 30 deg., as registered by pyrometers installed at eight dif-

ferent points in the furnace. A unique feature of the installation is a door which when opening sinks into a pit so as not to interfere with the crane when handling large circular work in and out of the furnace.

Welded articles are heated gradually to about 75 deg. above their upper critical, thus relieving working stresses and refining the grain. Considerable variation in the relation between strength, hardness and ductility is possible, as is well known, by proper control of heating times, temperatures, and cooling rates. It is unnecessary to expand on this point, important though it be, for the principles of heat-treating low-carbon steel articles are the same, whether the piece be hammer welded or merely forged.

TESTS ON WELDS

The excellence of well-made seams joined in this manner is becoming generally acknowledged. Numerous tests of hammer-welded joints have been made, and seldom show an efficiency less than 90 per cent of the strength of the material. It is reasonable to expect high strength from such joints, since the method used evidently does much to remove those three chief causes of defects in forge-work—viz., insufficient care and labor by the smith, poor control of the heating flame and temperature of the work, and lack of accurate heat-treatment of the finished piece.

Blaw-Knox Co. in its boiler shop has a test pit and high-pressure pumps for testing closed tanks, and in addition the hammer-welding department contains a long testing press for proving open-ended pipes up to 6 ft. in diameter and 40 ft. long at any pressure under 1,500 lb. per sq.in. After a pressure of 50 to 100 per cent in excess of the working load has been applied, the seam is struck vigorously several times with a 10-lb. sledge. This would not only lay bare many a defect which would not be detected by a static load, but actually subjects the whole structure to a considerable impact, as is evident by the pressure gage jumping about 100 lb. at each blow. It is important to note that such testing should never strain the vessel much more than 80 per cent of the proportional limit of the material, otherwise the metal will become somewhat brittle due to cold work.

Fig. 8 shows a pot for annealing wire which after

FIG. 7. ANNEALING FURNACE FOR LARGE TANKS

completion was tested somewhat above its elastic limit. Well-marked Lüder's lines were then found to cover the entire surface, passing through the longitudinal and circumferential welds (whose general position is shown by the arrows) without appreciable distortion. This is a very elegant demonstration of the homogeneity of

FIG. 9. LUDER'S LINES CROSSING WELD ON POT OVER STRAINED IN TESTING

weld and body plate. Another evidence of quality in the weld is the fact that many annealing pots similar to this have been made of straight pipes, the double bell at the top having been expanded without injury or extra stretch at the weld.

WELDED ARTICLES

Modern industry requires vessels which withstand considerable temperature or mechanical strains and yet remain impervious to penetration by contained fluids or surrounding gases. Blaw-Knox Co. specializes in the manufacture of such articles.

Thin wire and sheet must be annealed during and after manufacture. A small amount of surface oxidation would be fatal, especially as the gage becomes finer and finer. Cast-iron annealing pots, with a carefully sealed lid, have been the standard utensil for guarding against this danger, but they warp badly on many reheatings, finally becoming impossible to seal effectively. Furthermore they are very heavy. Consequently hammer-welded annealing pots are gaining favor rapidly.

Riveted stills and tanks for volatile and light oils have given much trouble. No matter how carefully riveted and calked, the continual "weaving" of plate on plate caused by temperature variation in a setting, or by the jars incident to transportation, is almost certain to cause leakage, especially of the lighter fractions which penetrate almost microscopic openings. Such leaks have caused disastrous explosions or great losses in transit, and can be entirely overcome by hammer-welding.

Other heating vessels should be close to size and seamless in order that the heat conduction should be uniform throughout, or that there may be close clearance between walls and stirring or other mechanism. Cast vessels are thick, brittle and unsafe under any but moderate pressures, and hammer-welding is undoubtedly able to produce containers which will allow the designer of digesters and similar apparatus a much greater leeway.

Canadian Soap Industry in 1918

According to a report that has been issued recently by the Dominion Bureau of Statistics, Canada produced 108,316,748 lb. of soap in 1918, practically the whole of which was consumed in the dominion, only a little more than 1,000,000 lb. being exported. The dominion produced practically all its own requirements, only a trifle more than 5,000,000 lb. being imported.

The Pyrolysis of Some Hydrocarbons

BY FRED DENIG

THE purpose of this investigation was to determine the decomposition and vapor pressures of hexane, gasoline, kerosene and vaseline.

Vapor pressure data are of immense value to the refinery engineer in the design of pressure stills, cracking apparatus, etc. Such data are also of use to the internal combustion engineer who is interested in the history of the hydrocarbon during compression just before combustion. Roy Cross¹ published some curves several years ago showing the relation between pressure and temperature of several hydrocarbon mixtures when subjected to heat. These curves are about the only ones published and available to the average engineer interested in petroleum. It was thought desirable to recheck his values and to cite the distillation curve of the gasoline studied, which he failed to do. The curve for hexane has been determined, since engineers are prone to use this compound in many calculations involving gasoline. Vaseline was studied in order to determine whether it would decompose into fixed gases or into gasoline- and kerosene-like substances.

The bomb used in the investigation was furnished by H. L. Doherty & Co. through the active interest of D. G. Brandt. It consists of a cylinder 17 in. long, 4

FIG. 1. EXPERIMENTAL BOMB

in. outer diameter and 3½ in. inner diameter. Fitted to the cylinder was a collar 1½ in. thick. A head plate served as a cover, having a groove cut into it to fit the cylinder. A ring of soft copper was fitted into the groove. The collar and head were drawn together by means of eight ½-in. bolts. The approximate volume of the bomb was 2 liters. The bomb was made of shell steel and had been tested out to 7,000 lb. per sq.in.

The bomb was charged with 500 c.c. of hexane. The hexane was Kahlbaum's hexane (normal), redistilled, and the fraction taken that distilled within a range of ± 2 deg. C. of 69 deg. C. It is to be noted that the hexane was not absolutely pure, but the best that could be obtained under the circumstances. Indeed it was the same hexane that Ipatiev used in his studies on the decomposition of hexane.

	Per Cent
Hydrogen	67.0
Ethylene	8.7
Methane	25.0

Weight of free carbon deposited, 22g. The bomb was charged with 454 g (1 lb.) of vaseline. The vaseline had a specific gravity of 0.876 at 22 deg. C.

hydraulic pressure by the makers. The head plate contained an opening for a bull nipple for the pyrometer couple and another opening for a $\frac{3}{4}$ -in. nipple that connected to the fittings. As shown in Fig. 1, this nipple is connected to a tee, which in turn was connected to a pressure gage on one side and a pressure release valve and valves on the other side.

When cold no trouble was experienced in making the bomb tight and able to resist high pressures. However, when heated all joints were found to leak. Various expedients were tried to relieve the trouble. Finally we welded the bull nipple and the $\frac{3}{4}$ -in. nipple to the head of the bomb. For the leaks in all other connections we applied thin rings of soft copper. From

that time on we had no further trouble with leaks.

The bomb was placed in a Case gas muffle furnace. The upper limit of temperature was 425 deg. C., due to

the large amount of radiation from the walls of the furnace and the head of the bomb which protruded from the furnace.

To measure temperature a thermo-element of constantin-iron was used. The pyrometer was carefully calibrated before and after the experiments.

An American steam gage recording up to 3,000 lb. was used throughout the experiments. The gage was calibrated before and after the experiments, and a correction curve drawn. The corrections on this curve were the mean of the corrections as determined by the two calibrations.

METHOD OF PROCEDURE

A sample of the hydrocarbon was placed in the bomb and heated. Pressure and temperature observations were made at frequent intervals, and both heating and cooling curves obtained. The volume of gas formed was noted and the gas analyzed, and the liquid remaining was distilled and the fractions corresponding to the gasoline and kerosene cuts were treated for unsaturated compounds by the sulphuric acid² test and for aromatics.³ The tests applied were empirical in nature and serve only to give a general idea as to the constitution of the substances obtained.

All experimental values are tabulated on the accompanying tables, and curves showing the P - T relations are drawn for each substance. The curves for gasoline and hexane are shown on the same plot in order to show the marked difference in vapor pressures.

HEXANE

The curve for the vapor pressure of hexane has been determined experimentally up to 400 deg. C. (See Table I and Fig. 2.) Ipatiev³ heated hexane in a bomb quite similar to the one used in this experiment and states that at 510 deg. C. the hexane decomposes with explosive violence. In this paper he did not give the pressure-temperature data that he usually gave when he worked on the pyrolysis of different substances. For this reason it was determined in this experiment. Due to the large size of the bomb 425 deg. C. was the limit of temperature obtainable in the furnace used.

GASOLINE AND KEROSENE

In examining the P - T curve for gasoline (see Table II and Fig. 2), it is to be noted:

1. No decomposition took place throughout the range that the gasoline was heated, the product obtained after heating having exactly the same distillation curve as the substance placed in the bomb, and the cooling curve being exactly the same as the heating curve. Had the gasoline "cracked" the cooling curve (P - T) would lie above the heating curve.

2. The curve obtained is not a straight line, or in other words gasoline vapor does not follow Boyle's law. This fact is mentioned because Cross⁴ apparently obtained a straight line relation. He does not state whether he obtained his curve by experiment or by calculation.

Examination of the kerosene vapor pressure curve (see Table III and Fig. 2) shows a sharp bend upward. This sudden change in direction of the curve indicates decomposition. Analysis of the product after heating

shows the same fact. The decomposition point of kerosene is very close to its boiling point, so naturally decomposition is expected. It is interesting to note that Cross also obtained a straight line as he did in the case of gasoline.

VASELINE

Vaseline was studied in order to determine whether it would break down into a large amount of fixed gases or whether it would form a large amount of light products and a relatively small amount of fixed gases. (See Table IV and Fig. 2.)

The vaseline broke down almost completely to gasoline and kerosene, 81 per cent by volume being recovered. Of this fluid mass found in the bomb 34 per cent distilled off within the gasoline range—i.e., below 150 deg. C.—and 54 per cent distilled within the kerosene range—i.e., between 150 and 300 deg. C. The combined gasoline and kerosene fractions contained by volume 20 per cent of aromatics and about 9 per cent olefins. This may be explained by the work of Ipatiev, who heated ethylene under pressure and found that the gas polymerized at a temperature range of 350 to 400 deg. C., producing paraffins such as hexane, heptane octane, higher olefins and cycloparaffins, together with high-boiling products of an unsaturated character. Probably what happens can be best explained by simply assuming that the vaseline breaks down into the lower hydrocarbons, principally ethylene and hydrogen. The ethylene immediately polymerizes into cyclic and aromatic compounds, as well as into the paraffins.

POLYMERIZATION

There is much that remains to be studied about polymerization and it deserves much more intensive study than has been given to it. It will probably explain as much as our present-day theory of "cracking." Pressure is probably the greatest factor in influencing polymerization. For instance, when kerosene was heated to 860 lb. pressure, the gas contained 27 per cent olefin, the fluid 14 per cent gasoline, while when the pressure was allowed to rise to 1,450 lb. and at practically the same temperature, the gas contained 2.5 per cent olefin and the liquid 25 per cent gasoline; the theory being, of course, that at the increased pressure the olefins rapidly polymerized into gasoline-like substances.

New Method for Drying Clay

Pottery plants at Devon and Cornwall, England, are now using a new method for drying clays, in which two metal drums are employed, one inclosed in the other. The inner drum is driven by mechanical means, and while revolving, steam enters it at a few degrees above the temperature of boiling water. The clay is passed into the outer drum and comes into contact with the inner drum as it revolves, filled with steam. The water in the clay is evaporated and the clay dried quickly, the process being one measured in minutes. The waste steam, with temperature lowered through operation, is passed back to the boiler and utilized again under increased temperature. The labor saving in the new method, it is said, is considerable. The clay is fed into the drum automatically. The space requirements are only about one-eighth or one-tenth of the regular demands, and 1 ton of coal will dry about 45 tons of clay under the mechanical system described, as compared with about 8 to 10 tons by the customary method.

Electrolysis vs. Retort Smelting for Zinc*

BY FREDERICK LAIST

IT MAY be stated that the electrolytic zinc process is applicable to a great variety of ores and concentrates. Almost any ore containing zinc can be treated, although, of course, it does not necessarily follow that the operation of extracting the zinc will be profitable.

When we first undertook the development of the electrolytic process at Anaconda for the beneficiation of our complex zinc-lead-copper-silver ores and the utilization of our surplus water power, I had very little idea that such a process could be applied commercially except when the concentrates were low grade and water power was obtainable at low cost. Later we found that we could purchase high-grade concentrates originating in the West in competition with retort plants; in fact, it is probably not too much to say that the future of the zinc business in the West is going to depend to a considerable extent on the development of electrolytic zinc.

FUTURE OF ELECTROLYTIC ZINC

With the development of the process and the extension of our operations, my optimism as to the future of electrolytic zinc has steadily grown, until now I am not sure that we will not yet see electrolytic plants operating on high-grade concentrates and actually producing their power by the combustion of coal or oil or gas.

This statement may seem somewhat extreme, but it is based on the following general premises:

1. The fuel required for distillation and reduction of a ton of zinc in a modern retort plant will, when burned in an efficient modern power plant, generate sufficient electric energy to deposit a ton of zinc from sulphate solution.

2. The labor required for producing a ton of zinc electrolytically from a given concentrate will be no more than one-third the labor required by the furnace method.

3. The total investment required to produce a ton of zinc electrolytically will, in general, be little, if any, greater than by distillation—it being assumed, of course, that both plants are constructed with a view to permanence.

4. The great purity of electrolytic zinc and the desirable qualities which it possesses by reason of its purity will, as they become better known, give electrolytic zinc a distinct advantage on the market to the detriment of less pure grades of zinc.

While the correctness of the above premises has not been absolutely proved, I have from time to time come into possession of data which lead me to believe that in the main they are not far off. An accurate comparison can, of course, be made only where all local conditions are known, such as character of ore to be treated, cost and kind of fuel, unit construction costs, etc.

ADVANTAGE OF THE PROCESS OVER RETORT PROCESS

A very important advantage of the electrolytic zinc process over the retort process, and which I have purposely not included in the above, as I wish to speak of it more at length, is better recovery. There has been a good deal of misunderstanding as to the recovery realized in existing electrolytic plants and a certain amount

of disappointment has been manifested at the apparently low recovery being made. At Great Falls, for example, the recovery is approximately 80 per cent; at Trail it is lower than this. This 80 per cent average recovery is, however, made up of recoveries of about 75 per cent on low-grade concentrates containing 30 per cent to 35 per cent zinc on the one hand and 85 per cent to 90 per cent on high-grade concentrates containing 50 to 55 per cent zinc on the other. In other words, the possible recovery depends entirely on the grade and composition of the concentrates undergoing treatment, and the actual recovery depends as well on the design of the leaching equipment and the facilities for washing. I have not the slightest hesitation in saying that on pure, high-grade Joplin concentrates a well designed roasting and leaching plant can make a recovery of 92 to 95 per cent of the zinc content, and that in general on any given grade of concentrate a better recovery can be made than is commercially possible by distillation.

It goes without saying that a lower grade concentrate can be successfully treated, since the operating costs of the electrolytic process are more nearly proportional to zinc content than those of the distillation process and the presence of lead and iron is much less detrimental.

EXPERIMENTAL WORK CARRIED ON

The recovery of zinc from low-grade, and to a lesser extent, from high-grade concentrates is one of the things which is receiving considerable attention at the present time, and the future will see great improvement in this direction. Experimental work is being carried on along two lines:

1. To cut down losses of insoluble zinc by more careful control of roasting, and to improve extraction and washing by better design of leaching plant equipment and flowsheet.

2. By subjecting residues to additional treatment for recovery of both soluble and insoluble zinc.

The latter development is particularly important where the residues are to go to the lead smelter, as the presence of zinc in such residues, apart from representing an economic loss in itself, is highly detrimental to the subsequent smelting operation. Its removal and recovery would, therefore, be a very decided step in advance. Experimental work at Anaconda and Great Falls indicates that a recovery of 75 per cent of the zinc in the residue may be expected, which would bring the over all recovery on even a low-grade (30 to 35) concentrate between 92 and 94 per cent.

ABILITY TO TREAT FINES

Another important advantage of the electrolytic process is its ability to treat fines. Whether we like it or not, the flotation process is bound to be resorted to more and more for the production of zinc concentrates, and these are necessarily very fine. So far from being a detriment as in the firing process, this condition is a positive advantage to the new process, so that at Great Falls we have in the past actually limited our purchases of outside material to flotation concentrates.

Where acid is to be manufactured, the less complete roast required for the wet process may present certain advantages and might under favorable conditions make unnecessary the use of muffle furnaces. Obviously, from the standpoint of recovery the presence of sulphur in the form of SO₂ is not detrimental. The only possible disadvantage from too much sulphate in the

*Extracts from an address given before the meeting of the American Zinc Institute, May 10, 1921.

calcine is the building up of acid in the solution system to the point where a discard of cell acid must be made. This actually happens at Great Falls and results in the loss of a small percentage of zinc. Both the acid and the zinc could be saved by evaporation of a small portion of the cell solution each day, and this will probably be done.

From what has been said, you can see that electrolytic zinc has made quite remarkable progress in the six years that have elapsed since the commencement of the experimental work on which the existing plants are based. From a war baby it has grown into an industrial process which has demonstrated its ability to produce zinc in competition with older processes and has unquestionably come to stay.

Technically, both metallurgically and mechanically, the existing plants are far from perfect, and much remains to be done. In all departments improvements can be made which will result in better recovery, better current efficiency and lower operating and plant costs. Such improvements are not problematical, but certain, and in many instances already roughed out.

A British View on Steel Foundry Furnaces

A CONTRIBUTION to *The Engineer*, Aug. 5, 1921, says that the starting of a foundry for the production of small steel castings presents many difficulties by reason of the many different factors in the problem which have to be taken into consideration. For example, electric steel, by virtue of its freedom from gases and great purity, together with its high pouring temperature, seems well suited for the making of very thin and light castings, especially so if the steel is run directly from the furnace spout to the molds. Furnaces of 1-ton capacity are possibly the most suitable size. Compare this proposal with the crucible process, which is also suitable for the purpose in view. The pots are usually of about 90-lb. capacity—larger pots have generally been abandoned. The steel can be obtained exceedingly hot, fluid, and free from gas, and if a proper selection of the raw metals is made the resultant steel is as free from impurities as electric steel. The making of very thin section castings presents no difficulty.

A very small electric furnace would be necessary were it desired to pour the whole contents economically with the furnace at its highest temperature. To transfer the whole charge to one large ladle and from it to fill the molds would be less satisfactory owing to the steel chilling, and the steel would tend to set before the whole charge was cast. On the other hand, the crucibles can be taken straight from the crucible holes, at their highest temperature, just when wanted.

Furthermore, several small electric furnaces, say of 1-ton capacity, would be necessary to obtain a large output of exclusively small castings, and the cost of operating small electric furnaces is relatively high. In the crucible process, on the other hand, the weight of metal per pot is standard, and the cost is not affected by the size. Hence a comparison of the two methods may result in favor of the crucible, but there are, nevertheless, particular cases in which the electric furnace has the advantage.

The bessemer system, with converters up to 1 or 2 tons capacity, also has its advocates, who claim many

advantages over the two previous processes for the production of small steel castings, particularly when side-blown converters are used. The total tonnage may be kept down to 1 ton, and the temperature may be made very high if necessary by the addition of high grade silicon after the initial heat from the original charge has been attained. Small converters, as compared with electric furnaces of similar capacity, could deliver over five times the tonnage in an equal time, and the quality may be as high. The success of the converter primarily depends upon the operator. A skilled blower can be relied upon to put charge after charge into the foundry well up to the schedule. With low sulphur and phosphorus in the charged materials, these objectionable elements need not be high enough to influence the quality unduly. Abnormally low sulphur and phosphorus can, of course, be obtained in the electric furnace, but it is only rarely that such extreme purity is required, and at a cost which purchasers will pay only in exceptional circumstances.

The usual bottom-blown bessemer and side-blown converter produce similar qualities of steel. Generally the side-blown converter produces the more fluid steel for small work, but the refining losses are from 5 to 10 per cent greater than in the bottom-blown converter. It is generally supposed that the "blown" process always absorbs unlimited quantities of oxides. This may occur with overblown charges, but rarely happens when the process is in the hands of skilled operators. As a matter of fact, with weighed additions of ferrosilicon and manganese, etc., the attainment of specified physical tests and analyses to specifications presents no difficulty.

THE OPEN-HEARTH FURNACE

The usual open-hearth furnace is not so successful for small castings. The extremely high temperature required cannot be obtained consistently without destroying the refractories and generally shortening the life of the furnace. The most successful type of open-hearth for small work is the Siemens special rapid, with a capacity of 1 ton. The producers are built on to the end of the furnace—the flame describing a horseshoe bend before passing back through the same end on the way to the regenerators. The ferro-silicon and manganese are allowed to melt on the banks and run down into the bath. The carbon is somewhat high—from 0.60 to 0.80 per cent, and occasionally up to 1 per cent. The steel is poured directly from the furnace. The furnace is tapped—great care being taken to keep the tap hole and the flow of metal not too large.

The furnace tap hole may be opened and closed many times in the course of a heat, the steel being kept hot in the furnace in the meantime. The refining losses are small, but high carbon, instead of higher temperature and lower carbon, condemns this process for many classes of small castings. This type of furnace, however, has been used extensively with great success for the production of colliery castings. The steel with low carbon is too sluggish and cold for casting small work, but with the addition of manganese excellent manganese steel can be obtained.

The basic bessemer and basic open-hearth furnaces are not a success for the production of small castings.

That the old method of crucible steel making can still more than hold its position against modern methods has been clearly proved, and there are large buyers of small castings who have tried all processes, but

return to their former founders—the crucible steel maker. The quality of crucible steel may be due to the protection of the molten steel from oxidizing gases, which is usually exhausted by charcoal addition, and also by the protection afforded the metal by the slag which may be in contact with a neutral atmosphere.

The price of small steel castings is generally governed by the amount of core making, molding, size and the difficulty in running, etc. Providing the castings are clean and of ample strength for their proposed use, analysis is rarely called for. Special prices are paid for alloys and special carbon castings, but there is only a very small demand for these things.

Generally speaking, the very costly and expensively operated plants cannot insure any higher price for their products on the recommendation of slightly lower sulphur and phosphorus. Specialists can obtain high prices, but steel founders are not all specialists. They have to consider their various inquiries carefully in view of their own risks and their competitors' prices.

Instrument to Measure Elongation of Broken Tensile Specimens

BY R. W. WOODWARD*

ANYONE who has made a large number of tensile tests of metals is well aware of the awkwardness and other difficulties encountered in the usual method of measuring the elongation of a broken tensile specimen. This method generally consists of holding the matched ends of the specimens in the hands or laying them on a bench, setting a pair of dividers to the distance between previously punched gage marks inclosing the fracture, and measuring the distance apart of the divider points by a scale graduated in hundredths of an inch. Obviously by this procedure the fractured ends are not held together as tightly as possible and the measured elongation is somewhat too large. Furthermore the reading of the setting of the dividers from the graduated scale is attended with some difficulties, and blunders are often made. Also the simple operation of dividing the measured elongation by the gage length to obtain the percentage elongation is susceptible of mistakes and in checking computations is quite often found to be wrongly performed.

To overcome the first-named source of error many laboratories use a clamping device to hold the broken specimens, but still measure the elongation by means of dividers and scale. The instrument described in this paper was designed to eliminate as far as possible all the above sources of error and is a direct-reading instrument for obtaining the percentage elongation of a fractured specimen.

It consists of a bed plate upon which are mounted a fixed head stock with a movable center and an adjustable tail stock, as shown in Fig. 1. By this means specimens up to a total length of 9 in. can be rigidly held together, eliminating all gap at the fracture. Above the specimen is a slide carrying two index points. One of these indices is fixed to the slide, while the other is movable on the slide. The movable index carries a pinion which engages a rack on the slide. Fastened to the pinion shaft is a pointer which moves over the scale graduated into fifty divisions. The rack and pinion are such that one revolution of the pinion advances the index exactly 1 in. The pointer is set

at zero when the indices are exactly 2 in. apart; one revolution of the pointer then corresponds to a movement of 1 in., or for a 2-in. gage length, to 50 per cent elongation.

In operation the slide is moved until the fixed index is set into one gage mark. (There are light springs on the indices to keep them normally above the specimen.) The movable index is then slid along the rod until it fits into the other gage mark. The reading of the pointer then gives directly the percentage elongation. The elongation may be readily determined with an accuracy of ± 0.1 per cent, while with the ordinary method the best that can be obtained is ± 0.5 per cent.

FIG. 1. MACHINE FOR MEASURING ELONGATIONS

The following table shows the applicability of the instrument and represents elongation values obtained by the methods noted on ten specimens taken at random from a large number of the type shown in Fig. 1.

Specimen	Per Cent Elongation Measured by		
	Special In trument	Dividers, Specimen Held in Hands	Dividers, Specimen Held in Clamp
Q6A.....	21.7	22.5	21.5
Q8A.....	22.4	23.0	23.5
M8.....	22.1	23.0	22.5
V8A.....	25.2	25.0	25.0
R6C.....	24.4	24.5	24.0
Q9C.....	19.1	19.5	19.0
A1A2.....	6.0	6.5	6.0
P4A.....	25.8	26.0	25.5
R2C.....	19.8	20.0	19.5
R8C.....	21.7	21.5	22.0
Average.....	20.82	21.15	20.85

These readings were all taken independently without a knowledge of the values obtained by the other methods. They show that high values for elongation are obtained unless the specimen is held in some form of a clamp. Incidentally in this short series of measurements the value for the elongation of Q8A for the method given last in the table was first read off the scale as 0.42 in. instead of 0.47 in., as later inspection of the results show it should have been. This is an inexcusable blunder, but one that is certainly bound to occur at times.

The time taken to obtain the above measurements was also observed, but was found to be practically the same for all methods—namely, six to seven minutes. However, if the elongation is measured on opposite sides of the specimens, a gain in time as well as in accuracy will be noted.

The advantages claimed for this instrument are:

1. Elimination of sources of errors and blunders.
2. Greater sensitivity in the measurement of elongation.
3. Greater reliance can be placed upon the results.
4. A saving in time.

While the instrument described here¹ is designed to take 2-in. gage length specimens, by a simple change of dials it can be adapted to other gage lengths.

¹Arrangements have been made whereby this instrument will be placed on the market by the Tinius Olsen Testing Machine Co. of Philadelphia.

*Physicist, U. S. Bureau of Standards.

Displacement Pump for Elevating Acid by Compressed Air

ORDINARY simple or even compound air lifts have their limitations for handling acids and other chemical solutions owing to the low factor of submergence frequently encountered. The saturation of the air by the acid has also resulted in undesirable fumes and in losses due to precipitation at the point of discharge.

These difficulties are avoided in the Sullivan displacement pump, a small demonstration model of which is shown in the accompanying figure. The pump consists

DISPLACEMENT PUMP FOR ACID

of two cylinders or tanks, A, A, with a common inlet and a common discharge opening, each provided with check valves. The tanks fill by gravity from the source of supply, B, and are alternately emptied of their contents by direct air pressure which carries the liquid being pumped to the desired elevation, C. The filling and emptying of the tanks is controlled by the Sullivan automatic switch, which is placed above the level of the acid and operated by air from a line independent of that which supplies the tanks. The operation of the switch, by alternately admitting compressed air to each tank, secures a continuous discharge of acid into the storage tank or basin.

The characteristics of this new pump are:

The liquid to be pumped does not come in contact with any moving parts, such as floats, except the inlet and discharge check valves.

Clearance losses are avoided, since the automatic switch leads the expanded air from the empty tank into the full cylinder before admitting live air to the latter, thus filling the lines and clearance spaces.

Power and time losses in overcoming inertia are obviated by this method of reusing the exhaust air, thus starting the acid before live air is admitted.

The speed of switching is governed effectively by an accessible valve, without other adjustment.

The air pressure to the switching apparatus is regulated by an independent diaphragm reducing valve, securing positive and equal timing of the switch movement, regardless of the pressure in the air receiver.

There is no precipitation loss or emulsification of the acid being pumped. The compressed air does not mingle with the liquid, but merely exerts direct pressure upon its surface.

The pump and exposed parts may be made up of steel, cast iron, bronze or other materials designed to resist the chemical action of the acid to be handled.

Pumps may be supplied for any capacity and lift, and for liquid of any specific gravity, within a wide range.

New Brown Cold Junction Compensated Pyrometer

THE Brown Instrument Co., Philadelphia, Pa., is placing on the market a new thermo-electric pyrometer, which is automatically compensated in the instrument for changes in cold junction temperatures and which includes means of setting the pointer of the instrument to zero in the usual manner.

This is an improvement on the method of cold junction compensation developed by Darling in England in 1909, and an improvement on a few subsequent developments for automatic cold junction compensation brought out since that time. These former methods afforded no means of setting the instrument to zero. It is customary on all electrical instruments, including millivoltmeters and pyrometers, to supply a zero adjuster to enable the user to set the instrument to zero, provided the zero has shifted, due to jars in transportation or with continual service.

Darling used what is called a Briguet spiral, a compound strip of two metals of different coefficient of expansion. The Briguet spiral was used to move the scale dependent on the change in atmospheric temperature surrounding the instrument, or as an alternative this Briguet spiral was mounted to act on the springs controlling the moving element of the galvanometer. Darling's device was never used to any extent, because it was evident that unless an instrument had a means of setting to zero, serious errors might result in the use of the instrument. Suppose, for example, the instrument pointer was standing at 110 deg. F., was the pointer standing at this position on the scale because the temperature surrounding the instrument was 110 deg. F., or was the temperature surrounding the instrument only 90 deg. F. and had the zero shifted 20 deg.? Naturally, no accurate temperature instruments could be obtained with this element of doubt.

The new Brown construction patented Dec. 28, 1920, includes a means of setting the instrument to its proper zero. This is clearly set out, for example, in claim 1, as follows: "In an electrical instrument, a pointer, a scale operatively arranged with respect to said pointer, means to automatically compensate said scale for changes in temperature surrounding said instrument and means for establishing a normal zero, whereby said pointer can be set to zero."

It is generally understood by all users of thermo-

electric pyrometers that the millivoltage or emf. developed by a thermocouple is dependent on the difference in temperature between the hot and cold ends of a thermocouple. To get accurate measurements of temperature, it is therefore necessary that the cold end of the thermocouple be maintained at a constant temperature or the instrument must be compensated for the changes in temperature at the cold junction of the thermocouple.

It is common practice to use what are known as extension or compensating leads, formed of material similar to the thermocouple, which will transfer the cold junction from the binding posts of the thermocouple to a distant point. Heretofore it has been necessary to locate the cold junction at the end of the extension or compensating leads in a cold well in the ground or in a compensating box, where the temperature can be maintained constant.

If the new Brown pyrometer, compensated for changes in temperature of the cold junction, is used,

INTERIOR VIEW OF BROWN COMPENSATED PYROMETER

the extension or compensating leads are brought to the meter. Changes in temperature at the end of the extension or compensating leads also take place in the meter itself, which can be compensated for this change in temperature.

There are two methods by which this compensation can be easily obtained. A portion of the scale of the instrument may be mounted on thermostatic material and moved, dependent on the change in temperature of the meter, and in this way automatic compensation may be had. Only a portion of the scale is moved and an index on the other portion of the scale denotes the normal zero of the instrument.

A Briguet spiral similar to that used by Darling may be mounted in the instrument, controlling the springs and moving element directly, and a second index controlled by thermostatic metal may be mounted on the scale. This index works with change in temperature exactly in relation to the movement of the pointer controlled by the Briguet spiral attached to the moving element.

In using the new Brown pyrometer, it is only necessary to bring the compensating or extension leads from the thermocouple to the instrument. After mounting the instrument, the instrument pointer is set by the zero

adjuster to correspond with the index on the scale. If the values for a thermocouple have been determined, based on a cold junction of 75 deg. F., the index will indicate 75 deg. F., provided the instrument is subject to this surrounding temperature. If the instrument pointer does not correspond with this index, it is set accordingly. When the temperature surrounding the instrument and the cold junction of the end of the compensating leads at the instrument rises to 90 deg. F., the index automatically rises to 90 deg. F., and the Briguet spiral attached to the instrument pointer causes it to move up to 90 deg. F., automatically adjusting for the temperature of the cold junction of the thermocouple.

It will be understood that any number of thermocouples with their extension or compensating leads can be brought to the one instrument having this automatic compensation. Likewise, recording instruments can be equipped with this automatic compensation and means for setting the pointer to zero.

Census Report on Phosphate Rock, 1919

Phosphate rock to the value of \$10,300,198 was produced in the United States in 1919, according to figures just made public by the Bureau of the Census. Sixty-five per cent of the total production came from Florida. Thirty per cent of the total production was mined in Tennessee. The remaining 15 per cent was produced in South Carolina, Idaho, Kentucky and Utah. The detailed figures, as given out by the Census Bureau, are:

Number of enterprises.....	48
Number of mines.....	69
Number of enterprises operating beneficiating plants in connection with mines.....	20
Mineral lands operated, total (acres).....	160,447
Persons engaged in industry, total.....	4,761
Proprietors and firm members.....	14
Salaried employees.....	374
Wage earners (average number).....	4,373
Wage earners Dec. 15 or nearest representative day:	
Above ground.....	5,764
Below ground.....	149
Power used (horsepower).....	49,639
Capital.....	\$72,733,956
Principal expenses:	
Salaries.....	761,423
Wages.....	3,900,966
Contract work.....	163,696
Supplies and materials.....	2,161,501
Fuel.....	1,739,833
Power.....	79,468
Royalties and rents.....	209,687
Taxes.....	347,580
Expenditures for development (included in the above items).....	353,237
Products, total value ¹	\$10,300,198
Phosphate rock:	
Quantity (tons, 2,240 lb.).....	1,988,975
Value at mine.....	\$10,292,990

Selected Bibliography on Oil Shale

A "Selected Bibliography on Oil Shale," compiled by E. H. Borroughs, bibliographer, and M. J. Gavin, oil shale technologist, has just been issued by the United States Bureau of Mines. The bibliography, which is designated as Serial 2,277, refers to about 300 articles, papers, reports and treatises bearing on the technology of oil shale, and selected chiefly from the literature of the years 1915-20. The references cited cover the oil shales of the entire world, and relate to the history of the industry; the geographic occurrence and geology of shale deposits; methods of mining, retorting, refining and utilization; the properties of shale and their determination; statistics of the industry; legislation and legal regulations; and economics. Copies of Serial 2,277 may be obtained free by addressing the Director of the Bureau of Mines, Washington, D. C.

¹ Includes value of other minerals produced and the amount received for miscellaneous work, services and power furnished other enterprises.

in the Chemical and Metallurgical Industries

Dinner to Delegates From American Engineering Societies to Great Britain and France

The homecoming of the delegates from the American Engineering Societies who went to Great Britain and France to present the John Fritz medal to Sir Robert Hadfield and to Eugène Schneider was celebrated by nearly two hundred engineers at a dinner Monday evening, Oct. 10, at the Hotel Pennsylvania, New York City. Representatives of the British and French governments and of foreign engineering societies gave the event an international aspect unique in gatherings of engineers.

J. Vipond Davies, president of the United Engineering Society, acted as toastmaster. Messages were received from Herbert Hoover, Sir Robert Hadfield, Eugène Schneider, the Institution of Civil Engineers, the Institution of Mining and Metallurgy and Mining Engineers, Captain Riall E. Sankey, president of the Institution of Mechanical Engineers; Magnus Howett, secretary of the Institution of Mechanical Engineers; the British Iron and Steel Institute, Engineers Club of London, Faraday Society, Viscount James Bryce, Arthur Neal, Member of Parliament from Sheffield; Jesse Merrick Smith, and A. E. Kennelly, exchange professor to France. The speakers were Ambrose Swasey, Charles F. Rand, F. B. Jewett, A. S. Dwight, John R. Freeman, all members of the deputation; Captain G. H. Armstrong, British Consul General; Gaston Liebert, French Consul General; G. C. Clapperton, representing the British Institution of Electrical Engineers, and Prof. Jacques Cavalier, spokesman for the French universities. The closing feature of the evening was the presentation by Gaston Liebert, the French Consul General at New York, of medals struck by the French Government in commemoration of the entente cordiale between the engineering societies of both countries to the following engineers: George S. Webster, Philadelphia, president of the American Society of Civil Engineers; Edwin Ludlow, New York, president of the American Institute of Mining and Metallurgical Engineers; Edwin S. Carman, Cleveland, president of the American Society of Mechanical Engineers; W. McClellan, Philadelphia, president of the American Institute of Electrical Engineers; Charles T. Main, Boston, chairman of the A.S.C.E. delegation; A. S. Dwight, New York, chairman of the A.I.M.E. delegation; Ira N. Hollis, Worcester, Mass., chairman of the A.S.M.E. delegation; F. B. Jewett, New York, chairman of the A.I.E.E. delegation, and Ambrose Swasey, Cleveland, general chairman of the deputation.

Protest Distilled Spirits Tax

Drug, industrial alcohol, flavoring extracts and confectionery interests have joined in a protest to the Finance Committee of the Senate against the proposal of the majority members of the committee to levy a flat tax of \$6.40 a proof gallon on distilled spirits, with a rebate of \$4.20 a proof gallon where it is shown that the spirits are to be used for non-beverage purposes. It was stated that such a proposal is not acceptable to the industries requiring pure ethyl alcohol in the manufacture of its products for the following reasons:

1. The House bill did not increase the tax on alcohol from \$2.20 per proof gallon, but provided for an additional tax of \$4.20 on each proof gallon to be paid by the person responsible for diversion of the spirits to beverage purposes. This, substantially, is as it should be, and legitimate manufacturers are not concerned in such penalty, regardless of the amount thereof. The proposal of the majority members of your honorable committee, however, would make law-abiding citizens criminals until they proved themselves innocent.

2. Said proposal would tie up for an interminable

period vast capital—as an illustration, approximately \$1,500,000 annually in the case of Parke Davis & Co., Detroit, alone—without ultimately adding one penny to the Treasury of the United States or aiding in the enforcement of prohibition and without recompense to lawful business for interest, additional clerical help and counsel fees incidental to keeping accounts and prosecuting claims for rebate; and in this connection consideration should also be given to the inevitable increased cost to the ultimate consumer of medicines, food products and other necessities of life in the manufacture of which alcohol is an essential factor.

3. Said proposal would unquestionably put out of business innumerable small merchants and manufacturers doing a reputable business but not possessing or able to borrow the necessary additional capital to finance themselves pending uncertain adjustments of alcohol rebate accounts.

4. As taxes on distilled spirits under existing law are payable by the distiller or proprietor of the bonded warehouse on withdrawal from bond and are sold to the trades tax-paid, said proposal if otherwise practicable, leaves open the question of how and by whom the \$4.20 is to be legally claimed by way of rebate.

5. Generally speaking, said proposal is based upon the theory that if all distilled spirits are lawfully used, the Government will receive only the present rate of \$2.20 per proof gallon, and that any additional revenue will come from those who violate the Eighteenth Amendment to the Constitution and the national prohibition act; therefore, from a national standpoint, what is gained by penalizing legitimate industry and making more expensive indispensable articles of commerce, especially when the integrity and lawful operations of manufacturers using alcohol in their processes are investigated before the federal prohibition commissioner issues to them the basic permit to obtain and use alcohol and exacts bond (obtainable only at exorbitant rates of premium) in a penal sum practically double the non-beverage alcohol tax involved and conditioned upon their lawful use of the chemical?

6. Said proposal is a prohibition measure pure and simple and will neither produce additional revenue nor add a tithe of discouragement to bootleggers, who could not obtain a drop of alcohol if the prohibition unit of the Internal Revenue Bureau administered effectively the national prohibition act, the purposes of which are well stated in its very title—viz: "An act to prohibit intoxicating beverages, and to regulate the manufacture, production, use, and sale of high-proof spirits for other than beverage purposes, and to insure an ample supply of alcohol and promote its use in scientific research and in the development of fuel, dye, and other lawful industries."

7. In the final analysis, why not encourage industry in the lawful use of a chemical raw material of paramount importance which is already taxed many hundred per cent above its cost of production and thereby materially increase the revenue?

The protest is signed by the American Drug Manufacturers' Association, the American Pharmaceutical Manufacturers' Association, the National Wholesale Druggists' Association, the National Association of Retail Druggists, the Manufacturing Perfumers' Association, the Proprietary Association, the Flavoring Extracts Manufacturers' Association, the National Confectioners' Association and the Industrial Alcohol Manufacturers.

Copper Shingle Production

The Anaconda Copper Mining Co. has established a department at its Washoe plant at Anaconda, Mont., for the manufacture of copper shingles, copper-zinc shingle nails and affiliated specialties, in an effort to broaden the market for copper products. The present production for the most part is of purely experimental character.

Further Data on the Oppau Disaster

According to a statement made by the Badische Anilin und Sodafabrik, in another warehouse at Oppau no less than 7,000 tons of sulphonitrate of ammonium (the compound which caused the damage in the recent explosion) remained absolutely intact, although the walls of the building were blown in and glowing fragments fell right into the contents.

A witness affirms that on the day of the catastrophe preparations had been made for splitting up a block of the compound by means of explosives. On the other hand, the double explosion leads experts to think that possibly the first explosion outside the warehouse, presumably in the neighboring sulphonitrate of ammonium factory, was the result of completely unknown causes, and that the principal explosion was brought about by fragments scattered by the first explosion.

As to the practice of blasting the hardened masses of the product, it is said that this operation had been carried out about 20,000 times at the Badische works and elsewhere and had been performed only the day before in the very warehouse in which the explosion occurred.

La Liberté of Paris learns from a highly qualified chemist who visited the works at Oppau two days after the catastrophe that it is a mistake to suppose that the explosion will have any notable effect on the German output of fertilizers and dyes. In the first place, the dye works, which are situated at a distance of 2 kilometers from the site of the explosion, suffered little damage and work was scarcely interrupted. Within a radius of 250 meters nearly all buildings were completely destroyed; from 250 to 500 meters serious damage was caused; beyond 500 meters nothing but reparable damage occurred. It is reckoned that in three months' time the production of ammonia and the manufacture of fertilizers can be resumed as previously.

As for the cause of the disaster, the French chemist said that he could offer no explanation. The salt in question, he was informed, was manufactured at the works before 1914 and numerous experiments had been made in order to test its non-explosiveness; it had been placed in barrels and set on fire, for instance, or an electric spark had been passed through it, but no sign was ever detected of any danger of explosion.

Recent Advances in Plant Chemistry

About one hundred members of the Rochester Section of the American Chemical Society met at Hobart College, Geneva, N. Y., Oct. 1. Prof. J. E. Lansing, director of the department of chemistry, discussed in a very interesting way the teaching of chemistry at Hobart College from 1822 to the present day, and Dr. Thatcher spoke on "Recent Advances in Plant Chemistry," in part as follows:

Undoubtedly the most serious handicap which biochemists have had in the attempts to study or duplicate the chemical processes which take place in cell protoplasm lies in the fact that we have thus far been compelled to work with mixtures of reagents in solution, contained in beakers, test tubes, etc., in which ionization and diffusion make a uniform chemical change throughout the entire reacting mass practically unavoidable. Recent advances in our knowledge of the colloidal condition make it plain, however, that even in so small a mass as the protoplasmic contents of a single cell there are thousands, if not millions, of colloidal compartments, separated from one another by membranes of variable and perhaps constantly varying permeability, in which a great variety of chemical changes may go on independently of each other.

It would seem to me, therefore, that the first requisite for up-to-date study of the chemistry of living things is a recognition of the structure of the cell as an essential factor in its synthetic operations, and that the first advancement toward an understanding of and possible duplication of the cell synthesis will require the successful reproduction of a colloidal mass having similar structure to that of cell protoplasm.

I believe that a proper mental picture of the organization and activity of a plant cell is suggested by the figure of a well-organized chemical factory, with the different trans-

formations which are involved in the whole process going on in different parts of rooms of the factory, with the raw materials systematically transported from one room to another as they are needed to keep each step in the whole process going at the proper rate, and with all the different parts of the whole factory working in smooth co-ordination with one another.

The raw materials for this factory are the mineral matter and water coming from the soil and the gases of the atmosphere; the intermediates are the simple carbohydrates and amino-acids; and the finished products comprise all of the varied compounds which are the results of cell protoplasmic activity and which are used by the plant for its nutrition, growth or reproduction.

The researches of botanists and chemists in the past have dealt with the nature of the compounds and the chemical changes which are involved in each separate process of the factory's operation. The principal problem now is to learn the nature and method of superintendence of the factory, whereby its operations are automatically regulated and altered so as to provide the proper output of all the varying products of the factory to meet the needs of the whole plant. We are as yet almost wholly in the dark concerning the regulatory agencies which control the rate and character of the synthetic processes of cell operation. We call these regulatory agents "catalyst," or "enzymes"; but as to what they are and how they act we know very little.

Furthermore, we have absolutely no idea, as yet, of the methods of intercommunication and of recognition of supplies and needs of raw materials or finished products whereby the factory output is varied in kind or quantity.

A further aspect of plant chemistry, the significance of which is easily apparent from the simile of the factory, is that chemical changes which are almost the exact antithesis of each other are going on simultaneously in every active plant organism, if not indeed in each individual plant cell. The synthetic production of complex organic compounds and the destructive oxidation of previously produced synergic foods to furnish energy for the synthetic processes go on simultaneously; just as, in any factory, there is consumption of fuel, wearing out of equipment, etc., during the process of manufacture of the factory output. This phenomenon, too, is readily understood on the basis of colloidal structure and emphasizes again the importance of recognition of this condition of matter as a necessary step in studies of protoplasmic activities.

New Jersey Chemists Meet

About 150 members attended the first regular meeting of the New Jersey Chemical Society at Newark on Oct. 10. Dr. H. E. Howe, chairman of research extension division of the National Research Council, talked on the history, organization and functions of the Council. Chemists individually and as members of the different scientific societies were urged to co-operate with the Council in its efforts to visualize to the manufacturer the importance of industrial research. Prof. Arthur W. Thomas followed with some instructive remarks and a general review of recent developments in colloidal chemistry. Dr. Thomas exhibited a number of interesting colloids and by the use of an ultra-microscope demonstrated some of their unusual properties.

Invitation to Engineers to Visit Liège, Belgium, in 1922

The Association of Engineers graduated from the technical faculties of the University of Liège will celebrate next year the seventy-fifth anniversary of its founding. On this occasion there will be scientific ceremonials and social gatherings, to which will be invited the engineers of the great Belgian schools and of allied and friendly countries. The most important events will be a scientific congress and a technical exposition, June 11 to July 14, 1922.

The congress will include sections on mines, metallurgy, mechanics, electricity, chemical industries, geology and public works. The technical exposition will have for its aim the showing of the important rôle played by engineers in works of the profession and in industry.

Contract for German Potash Signed

Six large manufacturers of fertilizer, according to information reaching the United States Potash Producers' Association, have closed a contract for 80 per cent of their potash requirements for the next season with the German syndicate. The price is understood to be very close to the pre-war level. The closing of this contract, it was stated, leaves comparatively little business to be divided between the French and American producers. No American producer of potash is able to compete with the German product at the price offered. It was stated that they would not attempt to enter the market at the present price level.

The delay in the passage of the tariff bill is blamed by the domestic producers for this large contract going to Germany. They contend that they would have been able to meet the price of the German potash had the duty carried in the tariff bill been in effect.

Data Wanted on Industrial and Technical Photography

A survey of industrial and technical photography is being prepared by John H. Graff, industrial photographer and photomicroscopist, Brown Co., Berlin, N. H. In order to supplement his own wide experience with that of others in this field, Mr. Graff requests those using photography in their plants or organizations to assist him with samples of different types of photographs used; a short statement of how and why photography is being used, as in field, office, plant or research; information as to how far an outside photographer is employed, or, if the users have photographic departments of their own, a history of the development of the same. Methods of mounting, filing and reference are important; also statements of the costs and upkeep of the departments and the value and importance of them.

All these data and information will be compiled to make a complete history of the development and uses of industrial photography.

Bureau of Mines Co-Operative Agreements

As co-operative agreements between the U. S. Bureau of Mines and outside agencies are terminated automatically at the end of each fiscal year, it is necessary to renew the agreements that are to be continued. Those thus far signed for the current fiscal year add more than \$250,000 to the bureau's appropriations for research work. Of more importance, however, than the actual money made available are the contributions of services of technical men, of laboratories and other equipment. The co-operative agreements of direct interest to the chemical industries are:

University of Alabama—To study the problems peculiar to the mineral industry in the Southern States, particularly those relating to non-metallic minerals and their by-products, steel, coal and coke.

University of Arizona—To study problems connected with the mining and smelting of low-grade copper ores of the Southwest, with particular attention being paid to sulphur dioxide leaching and the precipitation of copper from sulphate solutions.

As co-operative agreements between the U. S. Bureau of Mines and outside agencies are terminated automatically at the end of each fiscal year, it is necessary to renew the agreements that are to be continued. Those thus far signed for the current fiscal year add more than \$250,000 to the bureau's appropriations for research work. Of more importance, however, than the actual money made available are the contributions of services of technical men, of laboratories and other equipment. The co-operative agreements of direct interest to the chemical industries are:

University of Alabama—To study the problems peculiar to the mineral industry in the Southern States, particularly those relating to non-metallic minerals and their byproducts, steel, coal and coke.

University of Arizona—To study problems connected with the mining and smelting of low-grade copper ores of the Southwest, with particular attention being paid to sulphur dioxide leaching and the precipitation of copper from sulphate solutions.

University of California—To study problems including

the purification of copper sulphate solutions, the fundamental chemistry of chloride volatilization and reduction of iron oxides with gases. The chemical service laboratory handles the chemical end of the work at the mining experiment stations located at Reno, Seattle and Salt Lake City.

State of Colorado—To make investigations and to secure data regarding the production of oil from oil shales.

Cornell University—To study alloys, principally those of the non-ferrous type, and electric furnaces.

Ohio State University—To study means of increasing efficiency in the utilization of the mineral substances necessary to the ceramic industry, and to study means of substituting ceramic products of American manufacture for those now imported.

University of Utah—To study the volatilization process as applied to low-grade lead and zinc ores in Utah and as applied to the reduction of lead fume and to the recovery of silver, lead and copper.

University of Washington—To study, among other things, the use of Northwestern clays for ceramic purposes and the electrometallurgical problems of the Pacific Northwest.

Arizona Copper Co.—To study problems relating to the leaching of partly oxidized copper ores.

Central of Georgia Railway Co.—To conduct investigation of Georgia kaolins, to determine their suitability for pottery and other ceramic purposes; to conduct investigations concerning the suitability of bauxite clays and bauxites for refractory or other purposes.

Davison Chemical Co.—To investigate the possibilities of obtaining more complete recoveries of light oil from coke-oven gas for the production of motor fuels.

Combustion Engineering Corporation, New York—To study the combustion of powdered fuels.

Morris P. Kirk, Harbor City, Cal.—To study volatilization of silver and lead from ores, and the reduction of volatilized fume into metallic bullion.

Vanadium Corporation of America, New York—To investigate molybdenum steel.

The Welsbach Co., Gloucester City, N. J.—To investigate cerium alloys.

University of Montana—To study the industrial use of picric acid.

Fire Changes Paper Company's Water-Power Plans

On Saturday, Oct. 8, a fire of unknown origin destroyed the sawmill of I. M. Pierce & Co. at Orono, Me. Because of the distance the logs are now being driven, the mill will not be rebuilt near the present site. The sawmill, a very old one, became the property of the International Paper Co. a few years ago, as it desired to control the water at the mouth of the Stillwater River where it flows into the Penobscot. Arrangements were then made for the continuance of the sawmill, using steam and electric power, and the mill has been a busy place even during the recent depression.

The International Paper Co. uses the water for its Webster mill on the one bank of the river and for its mechanical pulp and hydro-electric plant on the other bank. With the elimination of the sawmill, it is now probable that the old log dam, which was already partly replaced by a higher concrete one at the flume intakes, will be extended across the river, allowing greater water storage and additional installation of pulp grinders and hydro-electric equipment.

The paper company began to operate one of the paper machines recently after being closed down since last spring by a strike. With the many men from the sawmill out of employment, it can be expected that many men from the paper mill, still on strike, will go back.

To Oppose Pollution Bill

Representatives of chemical industries will appear before the Committee on Rivers and Harbors of the House of Representatives on Oct. 25 to oppose a bill by Representative Appleby which, if passed, will make it illegal for manufacturing plants or ships to discharge oil and other refuse matter into any navigable waters of the United States. The passage of this bill, it is declared, would work the greatest hardship on a large number of chemical plants.

Civil Service Examination

Open competitive examinations are announced by the United States Civil Service Commission for the following positions: Metallurgist, \$4,000 to \$4,800 a year; associate metallurgist, \$3,000 to \$3,800; assistant metallurgist, \$2,000 to \$2,800; junior metallurgist, \$1,500 to \$1,800.

Applications on Form 2118 will be received until further notice. Papers will be rated beginning Nov. 1, and thereafter every two weeks until the close of the examinations.

Personal

HAROLD W. ABBOTT has resigned as technical supervisor at the Messina plant of the Aluminum Co. of America, to accept a similar position with the Stackpole Carbon Co., St. Marys, Pa.

JOHN BORG has been elected president of the Big Ledge Copper Co., New York, N. Y., and NELSON GRAY, vice-president and treasurer.

MIERS BUSCH, Philadelphia, Pa., a member of the firm of Shoemaker & Busch, has been elected a director of the Pennsylvania Salt Manufacturing Co., Philadelphia.

CHARLES E. CARPENTER, president of E. F. Houghton & Co., Philadelphia, Pa., addressed the Pittsburgh (Pa.) chapter of the American Society for Steel Treating at the Chatham Hotel, Pittsburgh, on Tuesday evening, Oct. 4.

E. M. A. CHANDLER, formerly with the Industrial Chemical Laboratories, Inc., of Hammond, Ind., has accepted a position on plant research work at the new North Chicago plant of the Abbott Laboratories.

DR. G. G. COLE, head of the chemistry department at Lynchburg College, Lynchburg, Va., has been elected a fellow of the American Association for the Advancement of Science. The honor has been accorded as the result of his extensive research work. He has been a member of the association for fourteen years.

DR. F. G. COTTRELL, head of the chemical activities of the National Research Council, sailed from France on Oct. 11. Dr. Cottrell has spent the summer studying various phases of the chemical industry in Europe.

OTTO EISENSCHIML, president of the Chicago Chemists Club, has just returned from an extended trip in Europe.

E. T. MARCEAU, chemical director of the N. K. Fairbank Co., has transferred his headquarters from Chicago to the New York office.

DR. JOHN MARTIN THOMAS was inaugurated president of the Pennsylvania State College, Oct. 14, at State College, Pa.

H. S. WITMER, who has been for several years in the chemical department of the N. K. Fairbank Co., in Chicago, has been given charge of the St. Louis branch factory.

The University of Maine, Orono, Me., has had the following recent changes in the chemistry departments: George Mervil Seeley, instructor, replacing L. J. Waldbauer, who has gone to McGill; Milton Roland Louria, instructor, replacing Norman F. Eberman, who has gone to Johns Hopkins; John Newell Crombie, instructor, replacing V. L. Kemmerer, who has gone to Thiel College.

Obituary

S. C. LINBARGER, for the past six years ceramic engineer of the Carborundum Co., Niagara Falls, N. Y., died at his home in that city on Saturday, Sept. 3, at the age of twenty-nine years. Mr. Linbarger was a very active member of the American Ceramic Society, at the time of his death being chairman of the committee on sections and divisions and president of the New York branch of the society. He was an authority in the field of refractories and abrasives, having developed the crucibles of graphite, clay and silicon carbide, carborundum saggers and made a number of other important discoveries.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, OCT. 17, 1921.

Trading in the chemical market during the past week has been somewhat spotty with intermittent periods of activity and dullness. There were few important developments uncovered, although the continued inquiry for miscellaneous products gave an encouraging aspect to the situation. Export shipments during the past few months on leading basic chemicals have shown a decided expansion and domestic buying has been well distributed among the various principal consumers.

CHEMICALS

Producers of *nitrate of potash* have reduced prices on the domestic refined material and are asking 7½¢@8¢. per lb. on the granular according to quantity. Prices on *bichromate of soda* showed a little firmer tendency and the market closed at 7¼¢@8¢. per lb. for small quantities. There were a few sales recorded by second hands at 7¼¢. per lb. The demand has shown a fair improvement during the past week and offerings have not been plentiful. Most dealers of *caustic potash* were asking 5¼¢. per lb. for the 88-92 per cent imported material, although some sales were transacted down to 5¢. per lb. While activity is not so general, as buyers have not been desirous to follow the advance, the market seems to be holding its own around recent advances. Most of the imported material recently shipped is reported sold on contract to large consuming interests. Sales of *solid caustic soda* were reported at \$4 per 100 lb., while some odd lot business has gone through at \$4.05@ \$4.15 per 100 lb. Inquiries are quite numerous in the market and the tone is holding quite firm. The export demand from South America has been very good and large tonnage sales were reported by several dealers. A good domestic demand is also recorded from leading consuming interests. At the works 3¼¢. per lb., basis 60 per cent, is quoted for prompt shipment. Dealers of *nitrite of soda* are shading prices slightly in various quarters and small quantity business is reported at 6½¢. per lb., ex-store. In most directions 6¼¢@7¢. was the prevailing quotation. The demand has not been active of late and this condition has stimulated competition among holders.

Manufacturers of *bleaching powder* continue to quote 2¼¢. per lb. f.o.b. works for large drums in carload lots and report conditions extremely favorable. A few producers report production sold up for the next few weeks, while others are barely able to meet the daily requirements. Imported material is quoted at \$1.90 per 100 lb. c.i.f. New York. Sales of *light soda ash* in single bags are being made at \$2.10@ \$2.15 per 100 lb. Barrels are moving at \$2.45@ \$2.50 per 100 lb. A good inquiry is noted around the trade and the market is holding quite firm at the above figures. Ash at the works was quoted at \$1.60 per 100 lb., basis 48 per cent, in carload lots. Prices on spot *oxalic acid* are heard from 15½¢@16¢. per lb. Sales were reported f.o.b. works at 15¢@15½¢. per lb., depending upon the brand and quantity. Inquiries are reaching the market in moderate volume, but seem to be only for small-sized lots. Sales of carload quantities of *silicate of soda* are reported by producers at \$2.90 per 100 lb., f.o.b. New York, for the 60 deg. Bé. The 40 deg. in drums is moving on the basis of 1¢. per lb. in carload lots and up to 1¼¢. in smaller quantities. Imported *sulphide of soda*, 60-62 per cent, has sold at 4½¢. per lb. during the week. The broken material was quoted at 4¾¢. per lb. Domestic producers quote the fused at 5¢@5¼¢. and the broken at 5¼¢@5½¢. per lb., according to quantity. Crystals, 30 per cent, are quoted at 3¼¢. per lb. for domestic material, while numerous lots of imported material for shipment have reached the market at 2½¢. per lb. c.i.f. New York. Leading producers of *borax* are making sales at 5½¢. per lb. for carload lots and 5¾¢@6¢. for smaller quantities, depending upon the brand

and seller. Producers of *Glaubers salt* report sales at 1½c. per lb. in bags and \$1.65 per 100 lb. in barrels for large quantities. Sales of smaller lots in bags are reported at \$1.75 per 100 lb. and \$1.90 for barrels. Manufacturers of *zinc carbonate* are placing business at 16@18c. per lb., according to quantity. The inquiry is moderate, although a fair volume of small lot business is being recorded. The demand for *camphor* has shown improvement during the past week and the spot market has responded readily to the increased buying power. At the close prominent importers reported sales at 76c. per lb. for the Japanese gum and up to 77c. for odd lots.

COAL-TAR PRODUCTS

Sales during the week in the coal-tar products industry have shown considerable improvement. Intermediates have been a shade better, but there still lacks the real snap to buying. Most consumers are merely covering current necessities and are operating in a conservative manner. Heavy resale stocks of naphthalene, phenol, beta-naphthol and aniline oil continue to depress any possible hope for recovery. The majority of the products tend more toward stabilization, although prices are not advancing. Competition still remains quite keen among second hands and manufacturers and quoted prices are seldom adhered to when firm orders are in the market. There are reports around the trade that slightly increased production of *benzene* will soon be available through the opening of a few more coke ovens. Production at present is far from normal and this slight addition will be welcome news to many consumers who are anxiously awaiting supplies. Inquiries from rubber and paint makers are quite numerous for benzene. Refiners are offering only for future delivery at 27@33c. per gal. Resale stocks are very difficult to locate and generally sell at 38@40c. per gal. Resellers of *phenol* have placed business at 8¼@8½c. per lb., but the general quotation heard is 9c. per lb. Government resellers still quote 12c. per lb. The demand for export is decidedly brighter. Stocks among second hands are large and considerable buying will have to be done before the market assumes a normal basis. Makers of *paranitraniline* are quoting 80c. per lb., although there are some who intimate that as low as 77c. per lb. would not be turned down on firm business. Resellers ask 77c., with sales at slightly lower levels recorded. Producers of *dimethylaniline* ask 45c. per lb., but sales among resellers have been made down to 41c. Inquiries seem to be more numerous than formerly and more active interest has taken place in the past few days. Sellers of *betanaphthol* show no disposition to quote below 31c. per lb., except on real round lot business. The demand shows signs of improvement and some fair selling was done during the week. The scarcity of benzene has forced some manufacturers to stop their production of *aniline oil* and the market has strengthened to some extent. Resale stocks, however, are quite heavy and considerable purchasing must be done before the market will show signs of any real strength. The general asking price is 18c. per lb., but there are confirmed reports of actual sales somewhat below this level. First hands quote *H acid* at \$1.10 @ \$1.15 per lb., but some selling is said to have been done under the inside figure. The demand has shown a slight improvement and some fair selling was done during the week.

VEGETABLE OILS

With the market for castor seed firm, crushers of oil were holding out for 11c. per lb. on the U.S.P. quality in barrels and 10c. for the No. 3 technical grade. Offerings of *chinawood oil* on spot were scanty and prices at best were merely nominal, ranging from 15@16c. per lb. The inquiry on spot was confined to small quantity lots only. Futures closed firmer, importers asking as high as 14c. per lb. for November-December shipments from the Orient, c.i.f. New York in hardwood barrels. The market for *coconut oil* underwent practically little change. Ceylon style oil in New York was available at 8½c. per lb. in sellers' tanks, nearby positions, while on the coast 8½c. represented the market on November forward business. Manila oil in bulk closed at 7½c. per lb. asked, coast basis, November-

December shipment, with little interest shown by buyers at this figure. Ceylon style oil in barrels was generally quoted at 10c. per lb. spot New York, with Cochin style oil held at 10½@11c. per lb.

The St. Louis Market

ST. LOUIS, Oct. 14, 1921.

There has been quite an improvement in the drug and chemical market during the past two weeks and from all indications this should continue. While orders are still small, they are more numerous. However, a slight increase in volume is perceptible.

Prices on a whole are firm and the general opinion is that they have now reached a level where they are no longer consistent with manufacturing costs and the tendency will be to advance rather than make reductions for the future.

ALKALIS

Caustic soda remains in good demand, the price of \$4 per 100 lb., basis 73 to 75 per cent solid, f.o.b. point of production. There has been no change in this item. *Soda ash* demand is still only fair, with manufacturers' market prevailing. *Bicarbonate of soda* and *sal soda* are moving slowly but with the *bicarbonate* the more active at \$2.60 per 100 lb. in less than carlots.

CHEMICALS, DRUGS AND PHARMACEUTICALS

The second-hand market an *acetphenetidin* seems to have cleared and a fair volume of business is being transacted. *Ammonia water*, 26 deg., continues to move in a regular way. A heavy demand for *sulphate ammonium*, *pure granular*, is now being experienced and large stocks should be carried. *Benzene* is in sold up condition, with producers accepting business for only small quantities. No futures—ruling price 35c. to 40c. per gal. *Bismuth salts* are moving beyond manufacturers' expectations. The *bromide* situation is none the worse and prices are firm. *Caffeine* is beginning to open, but competition still remains keen. *Carbon bisulphide* demand very strong, with prices ranging from 8@10½c. per lb., depending upon quantities. *Carbon tetrachloride* demand is good owing to the substitution of this material for carbon bisulphide, with price remaining at 12c. During the past few weeks there has been a substantial increase in the demand for *ethers*. *Formaldehyde* is moving very well. There is quite a movement of *glycerophosphates*. *Hypo* is moving in a routine way. *Hypophosphites* are beginning to move quite freely, due to the approach of the fall season and the heavy demand for tonics in which these commodities are used. *Iodides* are in good demand, especially the *potash salts*, for which there is a very heavy demand, undoubtedly due to the fact that Government surplus stocks are now exhausted. *Saccharine* is moving pretty well. *Salicylates* have shown an increase lately. *Sulphur* remains in easy demand and firm price due to high freight rates. *Zinc oxide*, *lead free*, is selling at 8c., with demand light.

ACIDS

The heavy mineral acids are now moving in large volume owing to the fact that many steel mills are again in operation and in all probability this demand will increase. A fair amount of business is being transacted in *phosphoric acid*. *Pyrogallie acid* remains in good demand. A small increase in *tannic acid* inquiries is reported. *Acid tartaric* remains the same.

VEGETABLE OILS AND NAVAL STORES

Castor oil continues in good demand with price firm at 11½c. in drums for No. 1 U.S.P. *Linseed oil* has declined to 73c., basis raw oil, ex-warehouse. The demand is for spot oil and in small quantities. *Turpentine* demand is routine, with prices fluctuating from 75@79c., ex-warehouse.

PAINT MATERIALS

The *lithopone* market is showing signs of life. Manufacturers are quoting 6½c. in carlots and 6½c. in less than carlots at St. Louis. The recent drop in the price of floated *barytes* has stimulated the demand, which is now very strong. Price \$23 per ton continues strong. *Red oxide* and *whiting* moving slowly, with nominal price prevailing.

The Iron and Steel Market

PITTSBURGH, OCT. 14, 1921.

A bit of a chill has crept over the iron and steel and allied industries in the past week or two. There is nothing to indicate that conditions have grown worse in any respect, or to make it propable either that prices are going to decline or production decrease. The new appraisal of the situation must be due to disappointment over expected further improvement not materializing.

From the monthly report of the American Iron and Steel Institute, giving the steel ingot production of thirty companies, it can be computed that production in September was at about 32 per cent of capacity, against about 30 per cent for August and 21 per cent for July. At the middle of July production must have been at about 19 per cent. The increase to an average of 30 per cent for August was quite satisfactory. Apparently it was dangerously encouraging, since September, following the midsummer period, could be expected to show a greater broadening in steel demand. September, however, has shown an operation, in steel production, at only about 32 per cent, while the rate now can scarcely be estimated at over 35 per cent.

STEEL PRICES

Superficially viewed, steel prices show distinct vagaries. Bars, shapes and plates show a firming up. Since the beginning of August it has not been particularly difficult to place an attractive order at about 1.60c.

Last month there were definite advances in both sheets and wire products, \$5 a ton on all descriptions of sheets, \$2 a ton on plain wire and \$3 a ton on barb wire and nails. Each line shows a new development this week. In sheets the independents are announcing another advance, \$5 a ton, effective not later than tomorrow. In wire products it develops that attractive orders can again be placed at the old prices ruling prior to Sept 12.

These movements seem rather confusing, but steel prices do not always move in direct harmony with the relation between the demand and the capacity to supply the demand. In bars, shapes and plates the demand has been light and is light. Mills allowed prices to go below cost of production, hoping to broaden the demand. Buyers have not responded, and now they are trying to get cost out of the little business that is available. In wire products specifications against the contracts booked prior to the advance are presumably somewhat unsatisfactory, hence some sellers are willing to make sales afresh at the old prices. In sheets the business booked before the advance of three or four weeks ago was in actual shipping orders, which are beginning to play out, and it may be inferred that the mills are trying the experiment of another advance, to encourage orders at present prices. As the sheet mills have been losing money, it is quite possible they will adhere to the advance now promised, and their allowing the market to get down to its low point last August, when their costs were somewhat higher than at present, may be explained away or left without explanation. Prices upon which the advance is to be predicated are 2.50c. for blue annealed sheets, 3c. for black and 4c for galvanized.

Demand for oil country goods has increased somewhat, this being attributed to recent advances in oil prices causing oil interests to plan some winter drilling, for which the material must be delivered in the next few weeks.

Railroads have announced reduction of 28 per cent in iron ore freight rates, effective Oct. 20, approximately equaling the 40 per cent advances of Aug. 26, 1920. As the furnaces have large piles of ore, the reduction does not involve an early reduction in the cost of producing pig iron. The railroads had their eyes on the fact that there is approximately 10,000,000 tons of ore on Lake Erie docks. Furnacemen feel that in the circumstances they have no occasion to reduce pig iron prices. They would welcome reductions in rates on coke and limestone, on which they are paying freight bills every day. Consumers of pig iron would welcome reductions in rates on pig iron, which is sold them f.o.b. furnace. Naturally the buying of pig iron is not stimulated, and the market is very quiet. The valley market is unchanged at \$20 for bessemer, \$19.25 to \$20 for basic and \$21 for foundry.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	—	\$0.40 - \$0.45
Acetone.....lb.	\$0.12½ - \$0.12½	.13 - .13½
Acid, acetic, 28 per cent.....100 lbs.	2.75 - 3.00	3.25 - 3.50
Acetic, 56 per cent.....100 lbs.	5.50 - 5.75	6.00 - 6.50
Acetic, glacial, 99½ per cent, carboys, 100 lbs.	10.50 - 11.00	11.25 - 10.50
Boric, crystals.....lb.	12½ - 13	.13½ - .14
Boric, powder.....lb.	13 - 13½	.14 - .14½
Citric.....lb.	—	.45 - .47
Hydrochloric.....100 lb.	1.25 - 1.50	1.60 - 1.75
Hydrofluoric, 52 per cent.....lb.	12 - 12½	.12½ - .13
Lactic, 44 per cent tech.....lb.	.09½ - .10	.10½ - .12
Lactic, 22 per cent tech.....lb.	.04½ - .05½	.06 - .07
Molybdic, C.P.....lb.	3.25 - 3.50	3.60 - 4.00
Muriatic, 20 deg. (see hydrochloric).....lb.	—	—
Nitric, 40 deg.....lb.	.06½ - .06½	.06½ - .07
Nitric, 42 deg.....lb.	.06½ - .07	.07½ - .07½
Oxalic, crystals.....lb.	.15½ - .16	.16½ - .17
Phosphoric, 50 per cent solution.....lb.	.13 - .13½	.14 - .18
Picric.....lb.	.20 - .25	.27 - .35
Pyrogallol, resublimed.....lb.	—	1.75 - 1.90
Sulphuric, 60 deg., tank cars.....ton	—	11.00 - 12.00
Sulphuric, 60 deg., drums.....ton	—	13.00 - 15.00
Sulphuric, 66 deg., tank cars.....ton	17.00 - 18.00	—
Sulphuric, 66 deg., drums.....ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, 66 deg., carboys.....ton	—	—
Sulphuric, fuming, 20 per cent (oleum) tank cars.....ton	21.00 - 22.00	—
Sulphuric, fuming, 20 per cent (oleum) drums.....ton	23.00 - 23.50	24.00 - 24.50
Sulphuric, fuming, 20 per cent (oleum) carboys.....ton	31.00 - 32.00	33.00 - 34.00
Tannic, U. S. P.....lb.	—	.75 - .85
Tannic (tech.).....lb.	.45 - .48	.50 - .55
Tartaric, imported crystals.....lb.	—	.26 - .27
Tartaric acid, imported, powdered.....lb.	—	.27½ - .28½
Tartaric acid, domestic.....lb.	—	—
Tungstic, per lb. of WO.....lb.	—	1.10 - 1.20
Alcohol, Ethyl.....gal.	—	4.65 - 4.90
Alcohol, Methyl (see methanol).....gal.	—	—
Alcohol, denatured, 188 proof.....gal.	—	.35 - .36
Alcohol, denatured, 190 proof.....gal.	—	.37 - .38
Alum, ammonia, lump.....lb.	.03½ - .03½	.04 - .04½
Alum, potash, lump.....lb.	.03½ - .04	.04½ - .04½
Alum, chrome lump.....lb.	.10 - .11	.11½ - .12½
Aluminum sulphate, commercial.....lb.	.01 - .02	.02½ - .02½
Aluminum sulphate, iron free.....lb.	.02½ - .02½	.03 - .03½
Aqua ammonia, 26 deg., drums (750 lb.) lb.	.07½ - .07½	.08 - .08½
Ammonia, anhydrous, cyl. (100-150 lb.) lb.	.30 - .32	.33 - .35
Ammonium carbonate, powder.....lb.	.07 - .07½	.08 - .09
Ammonium chloride, granular (white sal ammoniac).....lb.	.06 - .06½	.06½ - .07
Ammonium chloride, granular (gray sal ammoniac).....lb.	.06½ - .07	.07½ - .08
Ammonium nitrate.....lb.	.07½ - .07½	.07½ - .08½
Amylacetate.....gal.	—	3.25 - 3.50
Amylacetate tech.....gal.	—	2.50 - 3.00
Arsenic oxide, (white arsenic) powdered lb.	.05 - .06	.06½ - .06½
Arsenic, sulphide, powdered (red arsenic) lb.	.11 - .11½	.12 - .13
Barium chloride.....ton	44.00 - 45.00	46.00 - 50.00
Barium dioxide (peroxide).....ton	.20 - .21	.22 - .23
Barium nitrate.....lb.	.07½ - .08	.08½ - .09
Barium sulphate (precip.) (blanc fixe) lb.	.04 - .04½	.04½ - .05
Bleaching powder (see calc. hypochlorite).....lb.	—	—
Blue vitriol (see copper sulphate).....lb.	—	—
Borax (see sodium borate).....lb.	—	—
Brimstone (see sulphur, roll).....lb.	—	—
Bromine.....lb.	.27 - .28	.28½ - .30
Calcium acetate.....100 lbs.	2.00 - 2.05	—
Calcium carbide.....lb.	.04½ - .04½	.05 - .05½
Calcium chloride, fused, lump.....ton	23.50 - 24.00	24.50 - 25.50
Calcium chloride, granulated.....lb.	.01½ - .02	.02½ - .02½
Calcium hypochloride (bleach'g powder) 100 lb.	2.50 - 2.60	2.70 - 3.25
Calcium peroxide.....lb.	—	1.40 - 1.50
Calcium phosphate, tribasic.....lb.	—	.15 - .16
Camphor.....lb.	—	.76 - .77
Carbon bisulphide.....lb.	.06½ - .06½	.07 - .07½
Carbon tetrachloride, drums.....lb.	.10½ - .10½	.11 - .12
Carbonyl chloride, (phosgene).....lb.	—	.60 - .75
Caustic potash (see potassium hydroxide).....lb.	—	—
Caustic soda (see sodium hydroxide).....lb.	—	—
Chlorine, gas, liquid-cylinders (100 lb.) lb.	.08 - .09	.09½ - .10
Chloroform.....lb.	—	.40 - .43
Cobalt oxide.....lb.	—	2.00 - 2.10
Copperas (see iron sulphate).....lb.	—	—
Copper carbonate, green precipitate.....lb.	.19 - .19½	.20 - .21
Copper cyanide.....lb.	—	.50 - .62
Copper sulphate, crystals.....lb.	.05 - .05½	.05½ - .06
Cream of tartar (see potassium bitartrate).....lb.	—	—
Epsom salt (see magnesium sulphate).....lb.	—	—
Ethyl Acetate Com. 85%.....gal.	—	1.00 - 1.10
Ethyl Acetate pure (acetic ether, 98% to 100%).....lb.	—	.40 - .42
Formaldehyde, 40 per cent.....lb.	.11½ - .12	.12½ - .13
Fusel oil, ref.....gal.	—	3.25 - 3.75
Fusel oil, crude.....gal.	—	1.75 - 2.00
Glauber's salt (see sodium sulphate).....lb.	—	—
Glycerine, C. P. drums extra.....lb.	—	.14 - .15
Iodine, resublimed.....lb.	—	3.50 - 3.60
Iron oxide, red.....lb.	—	.10 - .20
Iron sulphate (copperas).....ton	18.00 - 19.00	20.00 - 23.00
Lead acetate.....lb.	—	.10½ - .12½
Lead arsenate, paste.....lb.	.09 - .09½	.10 - .11
Lead nitrate.....lb.	—	.15 - .20
Litharge.....lb.	.07½ - .08	.08½ - .09
Lithium carbonate.....lb.	—	1.30 - 1.40
Magnesium carbonate, technical.....lb.	.08 - .08½	.09 - .10
Magnesium sulphate, U. S. P. 100 lb.	2.50 - 2.75	—
Magnesium sulphate, technical, 100 lb.	—	1.10 - 1.75
Methanol, 95%.....gal.	—	.66 - .68
Methanol, 97%.....gal.	—	.70 - .72
Nickel Salt, double.....lb.	—	.12 - .12½
Nickel salt, single.....lb.	—	.14 - .14½
Phosgene (see carbonyl chloride).....lb.	—	—
Phosphorus, red.....lb.	.40 - .41	.42 - .45
Phosphorus, yellow.....lb.	—	.30 - .35
Potassium bichromate.....lb.	.11 - .11½	.11½ - .12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$.20 — .21	\$0.25 — \$0.28
Potassium bromide, granular..... lb.	.20 — .21	.14 — .20
Potassium carbonate, U. S. P..... lb.	.04 — .04	.22 — .25
Potassium carbonate, 80-85%..... lb.	.04 — .04	.05 — .06
Potassium chlorate, crystals..... lb.	.06 — .07	.07 — .10
Potassium cyanide..... lb.	.05 — .05	.26 — .28
Potassium hydroxide (caustic potash)..... lb.	.05 — .05	.05 — .06
Potassium iodide..... lb.	.07 — .07	2.60 — 2.75
Potassium nitrate..... lb.	.07 — .07	.08 — .09
Potassium permanganate..... lb.	.20 — .21	.22 — .23
Potassium prussiate, red..... lb.	.28 — .29	.29 — .30
Potassium prussiate, yellow..... lb.	.20 — .20	.21 — .22
Rochelle salts (see sodium potas. tartrate).....		
Salammoniac (see ammonium chloride).....		
Sal soda (see sodium carbonate).....		
Salt cake (bulk)..... ton		17.00 — 20.00
Silver cyanide..... oz.		1.35 — 1.38
Silver nitrate..... oz.		.46 — .47
Soda ash, light..... 100 lb.	2.10 — 2.15	2.20 — 2.50
Soda ash, dense..... 100 lb.	2.35 — 2.40	2.45 — 2.70
Sodium acetate..... lb.	.04 — .04	.04 — .05
Sodium bicarbonate..... 100 lb.	2.00 — 2.25	2.50 — 2.75
Sodium bichromate..... lb.	.07 — .08	.08 — .08
Sodium bisulphate (nitric cake)..... ton	5.00 — 5.25	5.50 — 6.50
Sodium bisulphate powdered, U.S.P..... lb.	.04 — .05	.05 — .06
Sodium borate (borax)..... lb.	.05 — .06	.06 — .07
Sodium carbonate (sal soda)..... 100 lb.	1.75 — 1.90	2.00 — 2.25
Sodium chloride..... lb.	.07 — .07	.08 — .08
Sodium cyanide..... lb.	.25 — .26	.27 — .30
Sodium fluoride..... lb.	.10 — .11	.11 — .12
Sodium hydroxide (caustic soda)..... 100 lb.	4.05 — 4.15	4.20 — 4.75
Sodium hyposulphite..... lb.	.06 — .06	.03 — .03
Sodium nitrite..... lb.	.06 — .06	.07 — .07
Sodium peroxide, powdered..... lb.	.25 — .26	.27 — .30
Sodium phosphate, dibasic..... lb.	.04 — .04	.04 — .05
Sodium potassium tartrate (Rochelle salts) lb.	.13 — .13	.13 — .13
Sodium prussiate, yellow..... lb.	.13 — .13	.13 — .13
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 — 1.15	1.25 — 1.40
Sodium silicate, solution (60 deg.)..... lb.	.02 — .03	.03 — .03
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 — 1.75	2.00 — 2.25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.04 — .04	.05 — .06
Sodium sulphite, crystals..... lb.	.03 — .03	.03 — .04
Strontium nitrate, powdered..... lb.	.12 — .13	.13 — .20
Sulphur chloride, red..... lb.	.05 — .05	.05 — .06
Sulphur, crude..... ton	18.00 — 20.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 — .08	.09 — .10
Sulphur (sublimed), flour..... 100 lb.		2.25 — 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 — 2.75
Tin bichloride, 50 per cent..... lb.	.18 — .19	
Tin oxide..... lb.		.38 — .40
Zinc carbonate, precipitate..... lb.	.16 — .16	.17 — .17
Zinc chloride, gran..... lb.	.09 — .09	.10 — .11
Zinc cyanide..... lb.	.42 — .44	.45 — .47
Zinc dust..... lb.	.11 — .11	.11 — .12
Zinc oxide, XX..... lb.	.07 — .07	.08 — .09
Zinc sulphate..... 100 lb.	3.00 — 3.25	3.30 — 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.15 — \$1.20
Alpha-naphthol, refined..... lb.	1.25 — 1.30
Alpha-naphthylamine..... lb.	.27 — .30
Aniline oil, drums extra..... lb.	.17 — .20
Aniline salts..... lb.	.24 — .25
Anthracene, 80% in drums (100 lb.)..... lb.	.75 — 1.00
Benzaldehyde U.S.P..... lb.	1.25 — 1.35
Benzidine, base..... lb.	.90 — 1.00
Benzidine sulphate..... lb.	.75 — .85
Benzoic acid, U.S.P..... lb.	.60 — .65
Benzoate of soda, U.S.P..... lb.	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 — .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 — .28
Benzyl chloride, 95-97%, refined..... lb.	.25 — .27
Benzyl chloride, tech..... lb.	.20 — .23
Beta-naphthol benzoate..... lb.	3.50 — 4.00
Beta-naphthol, sublimed..... lb.	.70 — .75
Beta-naphthol, tech..... lb.	.31 — .34
Beta-naphthylamine, sublimed..... lb.	1.75 — 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 — .17
Ortho-cresol, in drums (100 lb.)..... lb.	.25 — .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 — .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 — .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 — .50
Dichlorobenzene..... lb.	.06 — .09
Diethylaniline..... lb.	1.00 — 1.15
Dimethylaniline..... lb.	.41 — .50
Dinitrobenzene..... lb.	.23 — .27
Dinitrochlorobenzene..... lb.	.23 — .25
Dinitronaphthalene..... lb.	.30 — .35
Dinitrophenol..... lb.	.35 — .40
Dinitrotoluene..... lb.	.25 — .30
Dip oil, 25%, car lots, in drums..... gal.	.30 — .35
Diphenylamine..... lb.	.60 — .70
H-acid..... lb.	1.10 — 1.20
Meta-phenylenediamine..... lb.	1.15 — 1.20
Monochlorobenzene..... lb.	.12 — .14
Monoethylaniline..... lb.	1.60 — 1.70
Naphthalene crushed, in obls..... lb.	.05 — .07
Naphthalene, flake..... lb.	.06 — .08
Naphthalene, balls..... lb.	.08 — .09
Naphthionic acid, crude..... lb.	.70 — .75
Nitrobenzene..... lb.	.12 — .15
Nitro-naphthalene..... lb.	.30 — .35
Nitro-toluene..... lb.	.15 — .17
Ortho-amidophenol..... lb.	3.00 — 3.10
Ortho-dichlor-benzene..... lb.	.15 — .20
Ortho-nitro-phenol..... lb.	.75 — .80
Ortho-nitro-toluene..... lb.	.15 — .20
Ortho-toluidine..... lb.	.20 — .25
Para-amidophenol, base..... lb.	1.40 — 1.45
Para-amidophenol, HCl..... lb.	1.70 — 1.80
Para-dichlorobenzene..... lb.	.12 — .15
Paranitroaniline..... lb.	.77 — .80
Para-nitrotoluene..... lb.	.80 — .85
Para-phenylenediamine..... lb.	1.70 — 1.75
Para-toluidine..... lb.	1.25 — 1.40
Phthalic anhydride..... lb.	.40 — .50

Phenol, U. S. P., drums..... lb.	.08 — .10
Pyridine..... gal.	2.00 — 3.50
Resorcinol, technical..... lb.	1.50 — 1.60
Resorcinol, pure..... lb.	2.00 — 2.25
Salicylic acid, tech., in bbls..... lb.	.18 — .20
Salicylic acid, U. S. P..... lb.	.19 — .22
Salol..... lb.	.60 — .70
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 — .16
Sulphanilic acid, crude..... lb.	.27 — .30
Tolidine..... lb.	1.30 — 1.35
Toluidine, mixed..... lb.	.43 — .45
Toluene, in tank cars..... gal.	.25 — .28
Toluene, in drums..... gal.	.28 — .31
Xylidines, drums, 100 gal..... lb.	.40 — .45
Xylene, pure, in drums..... gal.	.40 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .30

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.19 — \$0.20
Beeswax, refined, dark..... lb.	.24 — .25
Beeswax, refined, light..... lb.	.28 — .30
Beeswax, white pure..... lb.	.36 — .42
Candellilla wax..... lb.	.24 — .25
Carnauba, No. 1..... lb.	.46 — .47
Carnauba, No. 2, North Country..... lb.	.24 — .25
Carnauba, No. 3, North Country..... lb.	.14 — .15
Japan..... lb.	.22 — .23
Montan, crude..... lb.	.05 — .05
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03 — .03
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 — .03
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 — .03
Paraffine waxes, refined, 125 m.p..... lb.	.03 — .03
Paraffine waxes, refined, 128-130 m.p..... lb.	.03 — .04
Paraffine waxes, refined, 133-135 m.p..... lb.	.04 — .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 — .06
Stearic acid, single pressed..... lb.	.09 — .09
Stearic acid, double pressed..... lb.	.10 — .10
Stearic acid, triple pressed..... lb.	.11 — .11

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.55 — 5.65
Rosin E-I..... 280 lb.	5.75 — 6.25
Rosin K-N..... 280 lb.	6.35 — 6.75
Rosin W. G. W. W..... 280 lb.	6.90 — 7.40
Wood rosin, bbl..... 280 lb.	6.25 — .
Spirits of turpentine..... gal.	.75 — .
Wood turpentine, steam dist..... gal.	.73 — .
Wood turpentine, dest. dist..... gal.	.72 — .
Pine tar pitch, bbl..... 200 lb.	6.50 — .
Tar, kila burned, bbl. (500 lb.)..... bbl.	11.00 — .
Retort tar, bbl..... 500 lb.	11.00 — .
Rosin oil, first run..... gal.	.35 — .
Rosin oil, second run..... gal.	.37 — .
Rosin oil, third run..... gal.	.44 — .
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	1.90 — .
Pine oil, pure, dest. dist..... gal.	1.50 — .
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 — .
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 — .
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 — .
Pine tar, ref., thin, sp.gr. 1.080-1.060..... gal.	.35 — .
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.25 — .
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 — .
Pinewood creosote, ref..... gal.	.52 — .

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 — .
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 — .
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 — .
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 — .

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.15 — 2.50
Blood, dried, f.o.b., N. Y..... unit	4.00 — .
Bone, 3 and 50, ground, raw..... ton	30.00 — 32.00
Cyanamide, f.o.b. works..... unit	4.50 — .
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 — 3.00
Nitrate soda..... 100 lb.	2.25 — 2.30
Tankage, high grade, f.o.b. Chicago..... unit	3.00 — 3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	5.00 — 7.50
Tennessee, 78-80 p.c..... ton	8.00 — 9.00
Potassium muriate, 80 p.c..... ton	38.00 — 40.00
Potassium sulphate..... unit	1.20 — 1.25

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 — .21
Upriver coarse..... lb.	.11 — .12
Upriver caueho ball..... lb.	.11 — .12
Plantation—First latex crepe..... lb.	.15 — .15
• Ribbed smoked sheets..... lb.	.15 — .15
Brown crepe, thin, clean..... lb.	.15 — .
Amber crepe No. 1..... lb.	.17 — .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 — \$0.10
Castor oil, AA, in bbls..... lb.	.11 — .11
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.14 — .15
Cocanut oil, Ceylon grade, in bbls..... lb.	.10 — .10
Cocanut oil, Cochin grade, in bbls..... lb.	.10 — .11
Corn oil, crude, in bbls..... lb.	.09 — .09
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07 — .07
Cottonseed oil, summer yellow..... lb.	.09 — .09
Cottonseed oil, winter yellow..... lb.	.09 — .10

Linseed oil, raw, ear lots (domestic).....	gal.	.68	—	.69
Linseed oil, raw, tank cars (domestic).....	gal.	.63	—	.64
Linseed oil, in 5-bbl lots (domestic).....	gal.	.71	—	.72
Olive oil, Denatured.....	gal.	\$1.15	—	\$1.20
Palm, Lagos.....	lb.	.07	—	.07 $\frac{1}{2}$
Palm, Niger.....	lb.	.06 $\frac{1}{2}$	—	.06 $\frac{1}{2}$
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.09

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

CAMDEN—The Camden Oil & Refining Co., recently organized, is perfecting plans for the construction of a new oil refinery in the vicinity of Pine Bluff, Ark., with initial daily output of about 500 bbl. It is estimated to cost about \$40,000. H. M. Jones is president.

California

LOS ANGELES—The Bradley-Wise Paint Co., 650 Santa Fe Ave., manufacturer of paints, varnishes, etc., has awarded a contract to Gordon La Barr, 2000 East Vernon Ave., for the erection of its proposed new plant at 49th St. and the Pacific Blvd., Vernon, estimated to cost in excess of \$50,000.

SAN FRANCISCO—The United States Metal Products Co., 330 Tenth St., manufacturer of metal specialties, has preliminary plans under way for the erection of a new 2- or 4-story plant, exact size still to be determined. It will be located on a site adjoining the present works.

Connecticut

WINDSOR LOCKS—C. H. Dexter & Sons, Inc., manufacturers of paper products, have taken bids for the erection of a new 1-story building at their plant, 21 x 140 ft. Greenwood & Noerr, 847 Main St., Hartford, Conn., are engineers.

Delaware

WILMINGTON—The Ricard-Brewster Oil Co. is completing the removal of its plant from Front and Orange Sts., to its new works at Fifteenth and Walnut Sts., where facilities for increased production will be provided. A 2-story brick addition has been constructed to the factory at the new location.

Florida

JACKSONVILLE—The American Collapsible Box Co., High Point, N. C. A. Vanden Boom, manager, is perfecting plans for the erection of its proposed new plant at Jacksonville, for the manufacture of corrugated boxes and containers. The machinery installation will cost about \$75,000.

CANAL POINT—The Florida Sugar & Food Products Co. will soon commence the construction of its proposed new sugar mill, to be 100 x 200 ft., to be equipped for a daily production of about 400 tons of cane sugar. N. K. Williams is construction engineer in charge.

Louisiana

SHREVEPORT—The United States Window Glass Co., Morgantown, W. Va., has construction under way on the superstructure for its new local plant, estimated to cost in excess of \$500,000, and plans to have the works ready for operation early in March, 1922.

MONROE—The McNichol Pottery & Crockery Co., Memphis, Tenn., J. M. Goff, representative, is considering the erection of a new plant in the vicinity of Monroe, estimated to cost in excess of \$150,000 with machinery.

Maryland

HAGERSTOWN—The Vicama Mica Co., 3 Hamilton Row, recently incorporated, is planning for the installation of new equipment at its properties in Virginia, comprising quarrying machinery, pulverizing equipment and kindred apparatus for mica production.

Michigan

MARYSVILLE—The Transue Williams Steel Forge Corp. will defer the erection of its proposed new local plant, plans for which are nearing completion, until early in the coming year. The works are estimated to cost about \$40,000. O. F. Transue, 562 West Ely St., is president and general manager.

DETROIT—The Solvay Process Co., Solvay, N. Y., is considering plans for the

early reopening of its local plant. It is said that about 1,500 operatives will be employed at the start.

DETROIT—The Champion Porcelain Co., recently organized with a capital of \$750,000 by officials of the Champion Spark Plug Co., as a subsidiary company, has acquired the plant and property of the Jeffrey-Dewitt Co., Detroit, manufacturer of porcelain specialties for spark plugs and other products. J. A. Jeffrey is president of the new company, and M. C. Dewitt, vice-president.

Missouri

KANSAS CITY—The Ferro Enamel Supply Co., 1101 Swetland Bldg., Cleveland, O., is considering preliminary plans for the erection of a new branch plant at Kansas City. R. A. Weaver is president.

ST. LOUIS—Fire, Oct. 5, damaged a portion of the building occupied by the Cole Chemical Co., on Laclede Ave. An official estimate of loss has not been made.

New Jersey

NEWARK—The United Butchers' Stock Rendering Co., 392 Jackson Ave., Jersey City, N. J., will take bids during the present month for the erection of its proposed new plant on property recently acquired at Newark, for the manufacture of soap, fertilizer and kindred products. It will be 2-story, 40 x 60 ft., and is estimated to cost about \$50,000 with equipment. David M. Ach, 1 Madison Ave., New York, is architect.

NEWARK—The United Color & Pigment Co., McClellan St. and Evergreen Ave., has filed plans for improvements and alterations in its plant, used for the manufacture of paints, dry colors, etc., estimated to cost about \$10,000.

New York

MECHANICSVILLE—The Duffney Brick Co., is having plans prepared for the erection of a new plant, with main building 2-story, brick and steel, to replace its works recently destroyed by fire, with loss reported at about \$200,000. Bayard & Massey, 75½ North Main St., are architects.

SYRACUSE—The Solvay Process Co., Solvay, has adopted 24-hour operating basis at its local works, with total production said to be in excess of that during the war period.

BINGHAMTON—The Achilles Tire & Rubber Co., Floral Ave., has awarded a contract to S. B. Price for improvements in its plant, replacing a recent fire loss, estimated to cost about \$15,000.

NEW YORK—The Fleischmann Co., 701 Washington St., manufacturer of yeast, will make extensions and improvements in its local plant, including laboratory, estimated to cost about \$35,000. C. Aubrey Jackson, company address, is architect.

Ohio

ELYRIA—The Waukon Rubber Co. is completing plans and will take bids at an early date for the erection of a new 2-story and basement plant for the manufacture of rubber goods, estimated to cost about \$75,000. The Akron Engineering Co., 92 East Mill St., Akron, O., is engineer. W. R. Huntington is president.

ZANESVILLE—The Studebaker-Wulff Co. is negotiating with the stockholders of the Rotary Tire & Rubber Co., now in receivership, for the purchase of the plant and property of the company.

Oklahoma

ARDMORE—The Magnolia Petroleum Co., Dallas, Tex., is planning for the erection of a new casinghead gasoline plant at Ardmore, to be of five-unit type, with power house, air compressors, pumping equipment, etc.

Pennsylvania

WILLIAMSPORT—Dittmar Bros., 618 Day St., manufacturers of composition tiles and kindred products, have broken ground for the erection of a new 2-story plant, 57 x 184 ft., at the foot of Susquehanna St., estimated to cost about \$45,000. William Dittmar is head.

PHILADELPHIA—Fire, Sept. 30, destroyed a portion of the plant of the Publicker Commercial Alcohol Co., Swanson & Snyder Sts. An official estimate of loss has not been made.

South Carolina

CHARLESTON—Fire, Sept. 27, destroyed a portion of the local plant of the Virginia-Carolina Chemical Co., with loss estimated at about \$27,000.

Tennessee

KNOXVILLE—The Knoxville Paper Box Co. has awarded a contract to Warsham Bros., Knoxville, for the erection of a new 1-story plant, 50 x 125 ft., for the manufacture of paper boxes and containers, estimated to cost about \$35,000.

MEMPHIS—Fire, Oct. 4, destroyed a portion of the potash manufacturing plant of G. N. Shepardson, North Seventh St., with loss estimated at close to \$25,000.

KNOXVILLE—The Knoxville Fertilizer Co. is perfecting plans for the erection of a new plant in the Vestal section, to be 154 x 350 ft., and equipped for an initial capacity of about 125 tons. Manley & Young, 814 West Hill Ave., are architects and engineers. James W. Dean is secretary and treasurer.

BROWNSVILLE—The Brownsville Cotton Oil Co. is planning for the rebuilding of the portion of its plant, recently destroyed by fire with loss estimated at about \$22,000. R. N. Bond is manager.

Texas

DALLAS—The Trinity Oil Corp. will commence work at once for the conversion of the skimming plant of the Eastland Oil & Refining Co., into a complete oil refinery and purposes to have the plant ready for operation early in the coming year, with capacity of about 4,000 bbl. a day. The Eastland properties were recently acquired by the Trinity Company.

HOUSTON—The Sinclair Refining Co. is planning for the construction of a new battery of high-pressure oil stills and auxiliary operating equipment on the Houston Ship Channel.

BURKBURNETT—The Texas Oil Refining Co. is planning for the rebuilding of the portion of its local plant, destroyed by fire, Sept. 17, with loss approximating \$30,000.

Virginia

NORFOLK—The Tidewater Glass Mfg. Co. has arranged for the immediate erection of a new 1-story plant, 50 x 200 ft., for the manufacture of glass bottles, and will take bids until Nov. 1 for the installation of equipment, including blowing machines, air compressor, motors and other manufacturing and operating machinery. T. C. Williams is vice-president and architect in charge. J. L. Welton is president.

West Virginia

WHEELING—The Bonita Art Glass Co. is completing plans for the erection of its proposed new plant, comprising two 1-story buildings, 60 x 80 ft., estimated to cost about \$35,000. George E. House is president.

New Companies

E. L. & J. F. DENNEBY, INC., Brockton, Mass., has been incorporated with a capital of \$25,000, to manufacture polishes for leather of all kinds, and kindred specialties. Edward L. Denneby is president, and James F. Denneby, 98 Warren St., treasurer.

THE LAKANTYAS OIL CO., Room 800, 108 South La Salle St., Chicago, Ill., has been incorporated with a capital of \$1,500,000, to manufacture petroleum products. The incorporators are Paul N. Dale, C. C. Taylor and Eric L. Anderson.

THE STENNO CARBON PAPER CO., Salem, Ore., has been incorporated with a capital of \$150,000, to manufacture carbon and waxed papers and kindred products. The incorporators are F. E. Thompson, C. K. Bland and F. H. Drake, all of Portland, Ore.

THE MARYLAND SOAP CO., INC., Baltimore, Md., has been incorporated under Delaware laws with capital of \$500,000, to manufacture soaps, soap powders, etc. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE ROCHESTER PETROLEUM PRODUCTS, INC., Rochester, N. Y., has been incorporated with a capital of \$50,000, to manufacture oil products of various kinds. The incorporators are T. M. Jameson, C. H. Miller and H. G. Freeman, Rochester. The

company is represented by Theodore Jameson, Wilder Bldg.

THE RHODE ISLAND CRUCIBLE STEEL CO., Providence, R. I., has been incorporated with a capital of \$100,000, to manufacture steel products, castings, etc. The incorporators are George C. Hagstrom, Albert B. Benson and Carl A. Hagstrom, 185 Oakhill Ave., Pawtucket, R. I.

THE FIBRE TIRE & RUBBER CORP., New York, N. Y., has been incorporated under Delaware laws with capital of \$3,000,000, to manufacture rubber products, fiber specialties, etc. The company is represented by Arthur W. Britton, 65 Cedar St., New York.

THE MINERAL CARBONIC GAS CO., Jersey City, N. J., has been incorporated with a capital of \$200,000, to manufacture carbonic gas and affiliated products. The incorporators are H. W. F. Lorenz, Alexander Hynd and William Hall, 164 Broadway, Jersey City.

THE ATLAS CLAY PRODUCTS CO., INC., Atlas (Genesee Co.), Mich., has been incorporated with a capital of \$30,000, to manufacture burned clay products. The incorporators are W. T. Shonk, Redford, Mich.; and M. B. Goodrich, 1090 Sheridan Ave., Detroit, Mich.

THE WATERPROOFING CO. OF AMERICA, INC., 80 East Jackson Blvd., Chicago, Ill., has been incorporated with a capital of \$25,000, to manufacture waterproofing compounds and kindred specialties. The incorporators are A. N. Lustig, M. M. Rappaport and Fred Sprinkman, Jr.

McLANE BROS., MCCARTHY & SHEEHAN, INC., Whitman, Mass., has been incorporated with a capital of \$60,000, to manufacture leather products. The incorporators are William T. McLane, James J. Sheehan and Philip M. McLane, Abington, Mass.

THE LUSTRE ART GLASS CO., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture glass products. The incorporators are P. Frank, C. Vahlsing and W. S. Overend, 34 Nassau St.

THE FENG LABORATORIES, INC., New York, N. Y., has been incorporated with a capital of \$5,000, to manufacture chemical specialties. The incorporators are A. Lapidus, L. Weinstein and M. Lindeman. The company is represented by Fowler & Hoerner, 27 Cedar St.

THE PHILADELPHIA VINEGAR CO., Philadelphia, Pa., has been incorporated with a capital of 2,000 shares of stock, no par value, to manufacture vinegar and affiliated products. The company is represented by the New Jersey Corp., Guarantee & Trust Co., 419 Market St., Camden, N. J.

THE CHERRY RIDGE BRICK CORP., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture brick and other burned clay products. The incorporators are G. Stewart, J. W. Collopy, Jr., and A. R. Prendergast. The company is represented by John Ingle, Jr., 2 Rector St.

THE FRENCH-WITTUSEN CO., INC., Utica, N. Y., has been incorporated with a capital of \$25,000, to manufacture glassware products. The incorporators are W. S. G. B., and M. M. French, Utica. The company is represented by Colegrove & Baker, attorneys, Utica.

THE ANTI-GLARE ACCESSORIES CO., Indianapolis, Ind., has been incorporated with a capital of \$20,000, to manufacture light diffusers, glass specialties, etc. The incorporators are F. G. Phillips, M. D. Moore and W. E. Miller, all of Indianapolis.

THE CYL-LAP PRODUCTS CO., Baltimore, Md., has been incorporated with a capital of \$1,500,000, to manufacture abrasive products. The incorporators are Michael S. Coan, David L. Schiller and Robert F. Leach, Jr., Central Savings Bank Bldg.

THE PAN-AMERICAN CANADIAN LEATHER PRODUCTS CORP., Rochester, N. Y., has been incorporated with a capital of \$1,500,000, to manufacture leather products. D. Colbert, 51 Vick Park, Rochester, is the principal incorporator.

THE STATE OIL PRODUCING CO., Boston, Mass., has been incorporated under Delaware laws with a capital of \$300,000, to manufacture oil products. The incorporators are Willard Wayne, M. A. Colter and Henry C. DeWolf, Boston. The company is represented by the Delaware Trust Co., 900 Market St., Wilmington, Del.

THE NORTH AMERICAN POLISH CO., Los Angeles, Cal., has been incorporated with a nominal capital of \$5,000, to manufacture polishes, chemical products and kindred specialties. The incorporators are S. P. and B. B. Dorsey, and W. B. French, Pasadena, Cal. The company is represented by Ticknor, Carter & Webster, 304 Citizens Savings Bank Bldg., Pasadena.

Manufacturers' Catalogs

THE YOUNGSTOWN BOILER & TANK CO., Youngstown, O., calls attention to a well-illustrated bulletin, No. 400, printed in colors, which contains storage tank information, tables, designs and capacities.

THE NORTON CO., Worcester, Mass., has issued a 32-page booklet on Norton grinding machines. A general description is given, together with photographs of the different types.

THE CHAMPION ENGINEERING CO., Kenton, O., in a recent bulletin illustrates and describes its cranes, suitable for installation in foundries, fertilizer plants, tin plate mills, chemical plants, rubber and tire plants, sugar cane mills, copper smelting plants, etc. Mechanical data are given, together with photographs of cranes in operation in different industries and dimensions of the different types.

THE KING KNIGHT CO., San Francisco, Cal., calls attention to its publication "Oil Flow in Pipe Lines," by R. S. Danforth. This book comprises charts showing the pressure loss in different sized pipe lines, the conversion of viscosimeter readings, and the horsepower required for pumping. Price \$3.

BAKER & CO., INC., Newark, N. J., has issued the fourteenth edition of a booklet, Data Concerning Platinum, containing new tables, illustrations and matter descriptive of various appliances made of platinum.

THE M. W. KELLOGG CO., New York, N. Y., has issued an attractive booklet on Corrosion Tests, Grey Cast Iron and Chemi-Steel. Fifteen tests are described, together with a story on forge-welded chemi-steel and its industrial applications.

E. C. CODD CO., Baltimore, Md., in a new booklet describes chain furnace screens for furnaces and ovens. These screens consist of a multitude of individual strands of steel chain, which cuts off most of the heat rays but which does not interfere with the passage of the charge, nor the tools necessary for manipulation of the same.

THE HARDINGE CO., New York, N. Y., has issued Catalog 9, on "Pulverized Fuels." This bulletin is divided into three main sections—viz., the application of pulverized fuel to various burning problems, the principle of operation of the Hardinge mill and a discussion of the application of the Hardinge system for pulverizing fuels. This bulletin should be of interest to those who have problems pertaining to the generation large quantities of heat.

THE KINITE CO., Milwaukee, Wis., in a 24-page booklet describes and illustrates the use of Kinite for shear blades, re-drawing tools, blanking dies, draw dies, embossing and forming dies, broaches, etc. Kinite is explained to be a steel alloy having great resistance to wear, dense structure and close grain, air-hardening quality, freedom from distortion when hardening, and ability to take high polish.

THE LAKEWOOD ENGINEERING CO., Cleveland, O., in Bulletin 39 illustrates and describes Lakewood Model 701, storage battery tractor.

THE POWER SPECIALTY CO., New York, has just published a 32-page catalog on Superheated Steam and the Foster Superheater. In the fore part of this bulletin there is a discussion of the advantages of using superheated steam. This covers the benefits and savings to be expected with superheated steam on reciprocating engines and steam turbines. The Foster patented superheater construction is also fully explained and pictures and drawings are shown of modern installations of this superheater in all well-known types and makes of boilers. This same bulletin also introduces a new type of superheater which utilizes radiant heat from the combustion chamber of the boiler. A new special armored surface has made it possible to apply superheating elements of this kind to any type of water-tube boiler. The construction and advantages of this type are fully covered in the new bulletin No. 300.

THE PHILADELPHIA DRYING MACHINERY CO., Philadelphia, Pa., has just issued a new folder, which briefly illustrates and describes all the different types of ceramic and chemical driers this company builds.

THE DANIEL M. LUEHRS CO., engineer, Cleveland, O., has issued a bulletin on the Luehrs System of Liquid Heat Transmission. The system applies best in the form of circulating oil, heated electrically, where temperatures higher than steam are needed and where the application of direct heat would injure the product or be dangerous to apply. Automatic temperature control is provided. Another bulletin describes the system applied to oil roasting of food products, etc.

Capital Increases, Etc.

THE SUPERIOR ALUM WORKS, INC., Joliet, Ill., has filed notice of change of name to the Superior Chemical Co.

THE MERIDAN OIL CO., Indianapolis, Ind., has filed notice of dissolution under state laws.

THE BEAVER TILE & SPECIALTY CO., 442 West 42d St., New York, N. Y., is arranging for an increase in capital from \$45,000 to \$200,000. George B. Staples is president.

THE L. P. C. CHEMICAL CORP., a Delaware corporation, has filed notice to operate in New York, with capital of \$500,000, for the manufacture of chemical products. F. S. Mardon, 416 East 57th St., New York, is representative.

Involuntary bankruptcy proceedings have been instituted against the VALLEY FORGE MAGNESIA CO., Port Kennedy, Pa., manufacturer of magnesia products.

THE NAVAJO OIL CORP., Kansas City, Mo., has filed notice of change of name to the Interstate Refineries, Inc.

THE ZENITH FOUNDRY CO., Detroit, Mich., has filed notice of increase in capital from \$125,000 to \$200,000.

THE SCOVILL MFG. CO., Waterbury, Conn., manufacturer of brass products, has arranged for an increase in capital from \$5,000,000 to \$20,000,000.

THE AMERICAN AMMONIA CO., Boston, Mass., a Delaware corporation, has filed notice of increase in capital from \$950,000 to \$1,200,000.

Paul S. Ache, Erie Pa., has been appointed receiver for the CHIPPEWA OIL & REFINING CO., Beaver, Pa., in bond of \$50,000. The company's refinery will be continued in operation.

THE AMERICAN CORK SPECIALTY CO. and the COMPRESSED CORK CO., 461 Eighth Ave., New York, N. Y., have been merged with L. Mundet & Son, same address, manufacturer of kindred cork products.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT is holding its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS will hold its thirty-eighth annual convention at the Washington Hotel, Washington, D. C., Oct. 24-26.

INDUSTRIAL COST ASSOCIATION will hold its second national conference at Pittsburgh, Pa., Nov. 2-4, with headquarters at the William Penn Hotel.

INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA will hold its annual convention at the Waldorf-Astoria, New York, Nov. 1-5.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

The Threatened Railroad Strike

SOBER opinion in well-informed circles is to the effect that the railroad strike will not occur. We make no prophecy, but merely record the belief of those who have knowledge of facts on which they base their opinion. But even the layman without inside knowledge finds it difficult to imagine that the great railroad labor leaders can be so heedless of public opinion or blind to the consequences of their folly as to permit the threatened strike to be consummated. The issue is clear cut and thoroughly understood by the people and they will have none of it. They will show no sympathy for men who, at a time when industry is characterized by unemployment, would force millions of men into the ranks of the idle and paralyze the transportation system of a great nation. Fortunately it looks as though the Government is not to be cowed with threats, nor coerced or intimidated into a surrender. The threatened strike is plainly a revolt against the carefully considered decision of a Government agency. It is not the outgrowth of a controversy between employees and employers. It is a flat refusal to accept a reduction of wage ordered by the same board which a year ago granted an increase in wage. It is a plain refusal to play the game fairly and squarely. We have yet to see the first expression of public sentiment favorable to this attitude on the part of the unions, and while there may be some doubt as to whether the strike will eventuate or not, there is not the slightest question as to the outcome in case it occurs. Unionism will have dealt itself a blow from which it will not soon recover. The strike has been conceived in selfishness on the part of a small group of citizens and its success would be a crime against a nation that has been patient and long suffering with railroad workers.

Nobody To Blame

"**N**OBODY to blame." This, briefly, is the remarkable verdict of the Coroner's jury published after investigating the disaster to the ZR-2, which fell a blazing mass of junk into the River Humber a few weeks ago, burning out all but five of the fifty gallant lives aboard. "Nobody to blame." This is to say, the holocaust was either an accident not to be foreseen and guarded against, or an act of GOD. Surely such a verdict is the epitome of human stupidity or blasphemy!

In appraising this disaster engineers should remember several things: First, that the facts regarding this and similar occurrences are buried in governmental archives or known by uncommunicative officers. Second, that the first rigid balloon was built only fifteen years ago, and since then very few have been made alike; consequently accurate information about operating loads and stresses of necessity is lacking. Third, that the metallic portions of such machines are made of new alloys, about

whose manufacture and properties much yet remains to be known.

Our consideration should therefore be focused on two phases of the subject: First, Was the design adequate? Second, Were the materials trustworthy? Grave doubts exist on both these questions; an answer of "No" in either case would be fatal. Put bluntly, they were pitting unknown metal against uncertain loads. Is this an "act of God"?

As is perhaps common knowledge, the main skeleton of a modern airship consists of a series of giant bicycle wheels, wired to the center, and set at 15- to 20-ft. intervals. Longitudinal members hold them apart, and each rectangular side panel is wired on its diagonals. Inclosed are the gas bags, to the end are fixed the rudders and below are hung engines and cabins.

Now, from a design standpoint, a main structure can be so arranged as to be determinate to a definite assumed loading—i.e., all the stresses can be figured in the various properly disposed members when forces in definite amount are applied at definite points and in definite directions. Such forces would of course be chosen to represent what is thought to be the most severe operating conditions. Then all the parts can be designed to be safe against these stresses. Of course, one may assume a number of other loadings for other conditions of operation and figure the resulting stresses. Consequently a great many possible loadings would be analyzed in the design, and the final structure would provide for the heaviest combination.

Those who have wrestled with loads and deformations of continuous bridges or gas holders will realize that the problem of airship design is far from simple. The reactions to shifting loads depend upon the elasticity of the structure. When an airship is flying, various combinations of loads are present whether or not they have been so assumed in the preliminary calculations, and they shift themselves in amount and direction automatically with great rapidity, without asking leave of the designer. As our British contemporary *The Engineer* observes, even on the simplest assumptions "airship loadings are diabolically complex, and there is an amazing difference in principal shearing stresses between the inflated and empty condition." Imagine, therefore, what would happen in the members of a huge, fragile craft when buffeted by cyclonic gusts, or if a gas bag should burst when turning at high speed, thereby developing tremendous loads due to inertia. Still, "No one is to blame"!

The Engineer notes as matters of history that it is remarkable that airships have been consistently destroyed; approximately 100 have been constructed in the last fifteen years, the latest costing \$2,500,000, yet there are not a dozen fit to fly today. Forty of them were shot down during the war. While as naval scouts they have gathered valuable information, they are practically worthless in action when opposed by airplanes.

Twenty-six built between 1905 and 1914 came to grief, usually not while flying, but by storm or fire, occurrences which were also frequent during the war. Ten years ago British Naval Airship No. 1 broke amidships with the greatest ease while being taken out of the erecting shed. Yet now "Nobody is to blame"!

Enough for the features of pure design. We do not wish to accuse the designers of failing to act according to their best lights; but it will be evident from the history of airships that many elements of uncertainty surpass the assumptions made by the constructors. It is easily possible that a perfectly built structure would have failed because of excessive and unexpected forces. But what of the materials of construction?

In airships the members are built of $1\frac{1}{4} \times 1\frac{1}{4} \times \frac{1}{16}$ -in. duralumin angles. Duralumin is a peculiar alloy of aluminum and copper, with a little magnesium and manganese. It is "hardened" aluminum. It was discovered by WILM less than twenty years ago, and was in production in Germany before a list of its physical properties was published. That was in 1911, and for several years it was regarded as a metallurgical mystery—its behavior contradicted all expectations. It has the peculiar property of aging: after a proper quenching it increases in hardness and strength at room temperature, rapidly during the first few hours, but progressing at a slower rate for days. Such metal appeared to shock conservative metallurgists, who unconsciously judge the soundness and quality in metal by the degree of permanence of its properties.

In the last four or five years much scientific work has been done on such aluminum alloys, and much of it is published, so that the aging action is no longer so surprisingly bizarre. In fact, its various changes, with changes in composition and heat-treatment, have been co-ordinated with like facts known for many other common alloys, and duralumin has found its place in metallurgical theory without disrupting any of our fundamental conceptions. In fact the broad theory is being used daily to predict the expected action of this new alloy under untried circumstances.

So now it is known to the testing engineer that light aluminum alloys when rolled into thin sections "tear" very easily, making it essential that the metal's outer surface and inner texture be absolutely free of even microscopic notches, where concentrated stresses build up and all manner of evil results. Many American foundrymen have been driven near distraction when trying to make thin aluminum castings which didn't look like old-fashioned cast steel—an accumulation of bubbles held together by films of metal. They can appreciate the skill and sound technique required to cast thoroughly sound ingots, free from surface defects, and then roll these ingots into small shapes of really smooth surface and undamaged edges.

When we entered the war, our Government received and handed over to certain producing companies all that was then known in England and France regarding the manufacture and properties of these airship alloys; yet we are able to state advisedly that constant and intensive investigations directed by American metallurgists, second to none in the world, have only now enabled the production of duralumin of quality without a prohibitive number of rejections and the development of puzzling defects shortly after fabricating. A thoroughly dependable metal can be produced when its vagaries have been studied and mastered, but is it safe to assume that the metal entering into the construction of the ZR-2, cast

and rolled about three years ago, was any better or more dependable than our own technicians would have then produced?

Yet "Nobody was to blame"! Such a verdict is merely stupid. It must have been the refuge of a group of men, ignorant of engineering, and uninformed. But there must have been men present at the inquest who know more about the points at issue than the writer of these lines. Why did they sit silent? Perhaps the new legal philosophy of America has already entered their hearts: "I refuse to answer, by advice of counsel, on the ground that it might tend to incriminate me."

Signs of Promise

TWO events of the past week are calculated to hearten those who sit in the watch towers of chemistry and look for signs of promise. One was the dedication of the new chemical laboratory at Cornell University and the other the inauguration of a new course in chemical engineering in Sheffield Scientific School of Yale University. Each represents an influence set in motion, whose ultimate effects on science and industry cannot be foretold.

Unusual importance attaches to the new laboratory at Cornell because its donor is a New York banker, GEORGE F. BAKER, chairman of the board of directors of the First National Bank of that city. His identity was not made known until the building was dedicated and he himself laid the cornerstone with a silver trowel. Mr. BAKER has taken advantage of an unusual opportunity to contribute to the welfare of his generation, and not of his generation alone, but of his country for generations to come. No one can estimate the beneficence of such a gift to a science the application of which is daily proving itself to be the greatest single factor in our national welfare, whether for peace or war. His example may well be emulated by others with philanthropic ambitions; nor need the exhortation be limited to bankers alone. Beneficiaries of chemistry there are who can pay no better tribute to the industry in which they made their success than to endow instruction in chemistry. The example of Mr. EASTMAN and his gifts to "Tech" are still fresh in the memory.

Of chemical engineering at Yale much can be expected when the course becomes well established and facilities in the way of buildings, equipment and endowment funds are more generously provided. But what the institution may now lack in physical equipment it possesses in personnel and policies. Firm in their belief that instruction in chemical engineering should be directed mainly to the fundamentals of science and mathematics, with intelligent perception of their industrial applications, the faculty has adopted a policy that will do much to offset any lack in buildings or equipment. It is true that the course inaugurated is only of four years duration, but when it is remembered that until last year "Sheff" had only three-year courses in engineering, it will be seen that chemical engineering starts on advanced ground. Nevertheless we express the hope that the course may yet be extended to five or six years, or lacking this, that the students may be prevailed upon to return for post-graduate courses. We congratulate the institution on the inauguration of this department and express the hope that progress will always be evident in the development of the curriculum.

Development Of Transportation

WHAT is to be the greatest industrial work in the United States in the next decade? Prophecy is always hazardous at best, but a general survey seems to suggest that the greatest work will be the development, in the broad sense, of transportation.

There are various ways of guessing what men will do. One is to consider what they have opportunity to do, another what they need to do. Taking the latter tack, some data can readily be collected. The fact has been emphasized of late that normally there are about 2,000,000 persons engaged and drawing pay, if not actually at work during all of the Adamson eight-hour period, in rail transportation. That seems like a very large number out of a total of about 45,000,000 persons, including clergymen, public servants, teachers, office boys and others, engaged in gainful occupations according to Census Bureau showings, particularly when it is considered that there is a great deal of transportation besides rail transportation. It looks as if some improvement could be effected, releasing men for other work.

Then we have had a good bit of information about the freight cost of certain commodities, not many, but some, being more than half the total cost. That looks bad, although sometimes there are extenuating circumstances. Remembering that we are considering transportation in the broad sense, we have had many illustrations of the great difference between the value of food on the farm and on the table. Transportation and distribution are linked together—that is, they ought to be.

We have had preaching for many years about the great value of our natural waterways and of artificial waterways, with much citation of facts to show the economy. Apparently we need to utilize these advantages. One may ask why, if this needs to be done now, it did not need to be done just as much years ago. The fact is that a great change has occurred. Railroading is less than a century old. The greatest mileage of railroad constructed in a year was in 1887, only a third of a century ago. Once built, a railroad needed traffic. There was a very heavy overhead. It is only in quite recent years that the major portion of the railroad mileage has had to work at anything like capacity. There was no economic advantage in relieving a railroad of traffic it needed and could well handle, any more than there would be economic advantage in maintaining two parallel railroads when one could perform all the service desired.

Considering transportation in the broader sense, we have the obvious need of transporting power. We transport much coal at great expense, and use it inefficiently in small power units, when we need to consume the coal economically in large units at the mine and transport the power over a little copper wire, easily maintained.

From the other viewpoint that may be taken in attempting to guess what men will do in the next decade, that of what men have opportunity to do, we see the opportunity of operating railroads more economically, by better administration of freight cars so that they shall carry goods more miles per day per car, by electrification, by block signaling and by other improvements. We see the motor truck developed beyond a parity with the roads on which it should travel, so we have opportunity to build more and better roads.

We see waterways ready to be used, requiring only the building of boats and the installation of terminals. We see canal-building machinery and appliances that will produce given results with much less expenditure of man power than a quarter of a century ago.

We shall always be a restless nation, requiring much transportation of ourselves and our goods, so the market for transportation will always be a broad one. It is the very fact that transportation has been so urgently demanded in rapidly increasing quantities that transportation is not as efficient as it might be. If a commodity will be bought only if the price is low, efficiency makes the price low, but if it will sell anyhow, efficiency may be neglected. That has been the case with transportation.

Russian Chemists Sorely Need Help

SINCE printing an editorial on "Russian Chemists and Organic Chemistry" in our issue for Sept. 14, 1921, several letters have been received from their exiled brothers giving fragmentary information, often contradictory on account of incorrect rumors or tardy post. It appears that Dr. C. N. IPATIEFF served with the Russian Army during the great war, attaining the rank of General. Such duties of course prevented any scientific studies, and it has doubtless been difficult to continue them of recent years, lacking the necessary reagents and apparatus, which must be missing in a country whose very hospitals are stripped of bare necessities. A letter from London contains the sad news of his sickness and death, but another report through German channels speaks of him as still being well. Likewise, two reports have been received concerning Professor OSTROMISLENSKY, one saying that he is alive, but a clipping from a German paper states that he was killed at Moscow. We have also been given the shocking news that Professors KONOVALOV and ZELINSKY died of starvation and exposure as late as last year. Whether the Soviet rulers realize it or not, the loss of such human material is a serious handicap in the advancement of the "proletariat."

The proposal to send out a search party to find some of the survivors was not a flippant phrase, but a serious recommendation. Since HOOVER's relief forces have penetrated Russia, it has probably dawned upon the official mind that every philanthropic effort is not propaganda or an attempted economic penetration of Russia. Could not the American Chemical Society charge a committee with the duty of communicating with prominent members of the once-influential Russian Chemical Society, with the idea of discovering their necessities and formulating some plan of relief? It may be that many other brilliant chemists are approaching the fate of KONOVALOV and ZELINSKY.

Food supplies can now be forwarded to designated individuals through HOOVER's relief. Or it may be found that the greatest lack is equipment and scientific literature; in fact GORKY has been reported as saying that the greatest difficulty now existing for successful work in the arts and sciences is the absolute intellectual isolation of Russia. Public prints now assure us that the economic blockade has been lifted by all outside governments; international communications, though bad, should now allow the passage of necessary shipments, which doubtless would be forthcoming by generous donation if the facts were known.

Who will lend a helping hand?

Readers' Views and Comments

Sound Ingots and Rails as a Matter of Course

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have recently reverted to the valuable articles by Dr. G. K. Burgess, of the Bureau of Standards, Washington, D. C., and the editorial comment relating thereto appearing in the issues of CHEMICAL & METALLURGICAL ENGINEERING for Nov. 10, 17 and 24, 1920. These articles refer to the hundred tons of ingots the writer's firm sent over to America in 1913, made by what is termed the "Hadfield sound steel method." As Dr. Burgess' report showed, these rails were found to be of excellent quality and particularly free from defects.

There is no doubt that the system could be satisfactorily applied to the production of rails on a large scale. It may be added that there have been attempts to follow or copy my system, but unfortunately those doing so have generally left out some particular portion of the *modus operandi* recommended and practiced by my firm, the result being that the system has not had a full and proper chance of being investigated and tested on a large scale.

In view of the difficulties met with in the present type of rails used in roadbed construction, it seems regrettable that the important advantages of manufacture of this system, to which reference is now made, have not been fully and properly tested.

Notwithstanding the efforts adopted by the railroad company to inspect closely the "permanent way," as we call it over here (in your country "roadbed"), which

of course includes the rails, serious breakages of rails are constantly occurring. Besides, the heavy expense required to watch over the roadbed closely enough to prevent accidents is a matter of serious moment. Much of this inspection of steel rails would be unnecessary if steel sound and free from defects, as is quite possible, were used.

The increasing severity of the stresses and abrasion upon steel rails is brought home to the mind when one reads about the American coal train of such extraordinary length pulled by a Mallet engine and representing a string of no less than one hundred 120-ton cars of coal, which ran over the Virginian R.R. on Wednesday, May 25, from Princeton, W. Va., to Sewall's Point. The total trainload aggregated no less than 16,000 gross tons, and the length would probably be not far short of one mile.

In view of the fact that many rails are practically of tool steel temper—that is, as hard as is used for drills, chisels and other similar products—it will be understood that hard steel, which usually means brittle steel, is being severely stressed. In my opinion unless properly made and treated these will be liable to failure under these heavy loads and severe conditions.

At our recent conference at the Institution of Civil Engineers in London, several interesting papers on railroad matters were read, and discussion took place regarding rail failures. It was clearly proved that the microscopic cracks, from which most of these troubles originate, occur from want of care in the production of

FIG. 1. HADFIELD-JACK METHOD (PATENTED) APPLIED TO SHELL MANUFACTURE

From left to right is shown the special billet as cast; one of them sectioned longitudinally; a billet parted ready for breaking; the two portions ready for the press; after pressing, and then

two finished shells. It will be noticed that the forged blanks are somewhat longer than when finished, to furnish material for physical tests.

the original steel in the ingots from which the rails are rolled.

While it is not desirable to exaggerate the situation as some may have done, an improvement is certainly demanded. The following may seem a bold statement to make, but it can readily be proved to be true—namely, that given suitable plant and properly trained superintendents, it is possible to insure that only sound ingots would be passed to the rolling mill, also that every ton of ingots could be produced absolutely sound and from which nothing but sound rails would result. To put the matter in another way, it could be made quite practicable to accept a contract for 10,000 tons or, for the matter of that, hundreds of thousands of tons, of ingots, all of which would be sound and from which all the rails produced would be sound and free from defects.

The great point I wish to make is that under this system not a single ingot could get through which was not inherently sound and that this could be known before the ingot went into the rolling mill itself, whereas now the ingots vary in a very wide and dangerous degree in this respect and it is not known whether they are sound or not. Even if through any untoward accident of carelessness in the heats, some ingots were produced which would not meet the requirements, my point is that these would be known and detected before they reached the rolling mill. It will therefore be seen that the statement that if, say, a million tons of ingots was produced, every one of them would be sound and free from the troubles so frequently met at the present time, is, as shown in my various papers on this special subject, based not on imagination but on statements of fact and actual practice already carried out.

To deal with this rail problem adequately it is necessary to begin by inspection of the ingots—that is, this would not, as at present, be left until the rails themselves were produced, in most of which it is not possible to detect the flaws and imperfections, though they are there, as these cannot be seen.

The reply may be made, "Yes, but at what cost can this be done?" The answer to this is that with a properly systematized plant and operators, the extra cost involved would be comparatively slight. Besides, and in the end, with better methods such extra expense pays, as it is always economical to make and use good products. If some enterprising railroad would say, "We will try five or ten thousand tons of rails made in this manner," then the reply would be, "It can have sound rails, though naturally for small lots there would be, until manufacture was systematized on a large scale, some extra charge necessarily involved."

As further evidence of sound material, if such be needed, the attached Fig. 1 may be of interest to your readers. It shows the application of the Hadfield system to the casting of high explosive shell, of which my firm made hundreds of thousands during the war. It will be noticed that the blank in this particular photograph was not for one shell only, but for producing *two* in one blank, which greatly reduced the cost and time. Excellent results were obtained in making hundreds of thousands of these double blanks; notwithstanding the rapid production, there was practically an entire absence of waster shell from any cause, whether unsoundness, machining quality, mechanical properties or firing tests. As I claim in the case of ingots for rail making, an unsound blank is readily detected before any forging, pressing or other work is put on it.

Other photographs could be reproduced to show the application of the Hadfield system to 12-in., 15-in. and even larger shell cast in single blanks. Similar success to that mentioned above as regards 9.2-in. attended the production of these larger calibers.

In all these cases, especially as regards the larger shell, where the machining surface was so considerable, I do not remember my firm having a single rejection for unsoundness. In these larger calibers it was possible, as with the smaller ones, to determine quickly whether the blanks were in proper sound condition before putting a single minute of work on to them.

I claim that rails can be made in the same way just as sound as high explosive shell. Such rails would be quite sound, also free from segregation and other defects.

Credulochemistry

To the Editor of Chemical & Metallurgical Engineering

SIR:—Apropos of your recent editorial on "Credulochemistry," I would call your attention to the occurrence of this new science even in such an orthodox place as the Chemical Exposition. The following extracts from circulars which I received at a booth there illustrate some of the modern views of the adherents of this new science:

"There are, practically speaking, but two kinds of floor hardeners: One made of magnesium silicate, the other sodium silicate. Magnesium silicate is obtained from mica, hence cannot be any harder than mica, its base. While it acts very readily on the free lime in the cement, its hardening qualities are limited to the hardness of mica.

"Sodium silicate, which is used in — Floor Hardener with various other chemicals and gums, is spar. The purest form of spar known is red granite, which in turn is four times as hard as mica. In acting on the free lime in the concrete sodium silicate renders it four times as hard as when magnesium silicate is used.

"The hydrofluorine formed by the chemicals used in — Floor Hardener reacts powerfully on concrete and makes sand soluble and forms it into a mass as hard as flint."

The same "chemical" (?) company has made important discoveries in the organic branch of Credulochemistry, one of the most interesting of them being a linseed oil substitute, described in another circular, from which I quote a few sentences:

"The most general characteristic of — Oil is its property of depositing a thin but strong waterproof and porous-proof film; resisting weak acids, strong acids and full-strength acids, even if in solution form. It is high-resisting, non-explosive and less harmful (?) than linseed oil. It is a chemical and mineral oil, called a chemical and mineral oil because of its chemical properties [*sic!*] and purely mineral bases, and is superior in every way to linseed oil or any other paint oil made."

While it may be too much to expect the management of the Chemical Exposition to censor all of the printed matter distributed by exhibitors, yet there would not be much difficulty in general in picking out those who, from the nature of their business, would be most likely to perpetrate such atrocities in the name of chemistry, and keeping a watchful eye on their activities.

Oakmont, Pa.

FRANCIS C. FRARY.

Edward R. Weidlein, New Director of Mellon Institute

ANNOUNCEMENT has been made by the board of trustees of the University of Pittsburgh of the appointment of Edward Ray Weidlein as director of the Mellon Institute of Industrial Research. Mr. Weidlein has been acting director since the recent resignation of Dr. Raymond Foss Bacon, and prior to that time, since 1916, he served as associate director. Dr. Bacon, who left to engage in consulting chemical practice in New York, became director at the time of the death, in 1914, of Dr. Robert Kennedy Duncan, the first director of Mellon Institute and formulator of the Institute's successful system of establishing practical co-operation between science and the chemical industry.

Mr. Weidlein was a student of Dr. Duncan and later became an Industrial Fellow of the Mellon Institute. He has been associated intimately with the industrial fellowship system since 1909, and since 1916 has been a member of the administrative staff of the Mellon Institute. He has had a rich experience in the supervision of industrial research and enjoys a high national reputation as a specialist in the systematic investigation of the problems of chemical and physical technology. In addition, he brings to his new post of responsibility a boundless enthusiasm which has resulted from his studied devotion to the ideals of the industrial fellowship system of the Institute and from his naturally vigorous optimism.

Commenting on Mr. Weidlein's appointment, an officer of the University of Pittsburgh said: "His broadly sympathetic and luminous mind moves on a plane so near to that of Dr. Duncan, the founder of the Mellon Institute's system of research, that he knows this grand scheme of thought as it was developed; he brings to this important position and to the interpretation and diffusion of the Institute's industrial fellowship system such a happy combination of qualities as one very rarely meets with."

Edward Ray Weidlein was born at Augusta, Kan., on July 14, 1887. He was graduated at the University of Kansas, Lawrence, Kan., with the degree of Bachelor of Arts in the year of 1909; in 1910 he received the degree of Master of Arts. From Dec. 1, 1909, to March 1, 1910, he was engaged in a study of camphor, under the direction of the late Dr. Robert Kennedy Duncan. From March 1, 1910, to Oct. 1, 1912, he carried out a comprehensive study of the ductless glands, during the course of which he investigated epinephrin

from the whale. From Oct. 1, 1912, to Oct. 1, 1916, Mr. Weidlein was a Senior Fellow in the Mellon Institute of Industrial Research, having supervisory charge of all of the Institute's investigations on the metallurgy and hydrometallurgy of copper and having direction of the experimental plant at Thompson, Nev. In connection with this investigatory work Mr. Weidlein developed a process for the use of sulphur dioxide in hydrometallurgy which has aroused wide interest because of its economic importance.

On July 10, 1916, Mr. Weidlein came to the Mellon Institute at Pittsburgh as assistant director; on Oct. 1, 1916, he was appointed associate director and he became acting director in 1918, during the leave of absence of Colonel Raymond F. Bacon as Chief of the Technical Division of the Chemical Warfare Service, A.E.F. On March 12, 1918, Mr. Weidlein was appointed chemical expert for the War Industries Board. His activities on this board received the highest official commendation.

The forty-eight Industrial Fellowships or scientific investigations of important problems of manufacturing in operation at the Mellon Institute cover a wide range of problems in chemical and mechanical technology. Mr. Weidlein maintains a constantly active supervision over these researches. He has had this intimate relationship with the industrial fellowship system since its formulation by Dr. Duncan in 1917.

The following are some of the important journal contributions of Mr. Weidlein:

"Jamaica Camphor" (with H. W. Emerson), *Journal of Industrial and Engineering Chemistry*, vol. 4, pp. 33 to 36.

"Epinephrin From the Whale," *Journal of Industrial and Engineering Chemistry*, vol. 4, pp. 636 to 645.

"Recent Developments in Connection With the Use of Sulfur Dioxide in Hydrometallurgy," *Journal of Industrial and Engineering Chemistry*, vol. 9, pp. 1057 to 1058.

"Conservation of Heat in Power and Heating Systems," *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 24, pp. 295 to 300.

"Science and Industry," *Textile World Journal*, vol. 53, No. 44, pp. 186 to 191.

"The Industrial Fellowships of the Mellon Institute," *Science*, N. S., vol. 47, No. 1219.

Mr. Weidlein's inventions in the field of the hydrometallurgy of copper are claimed in U. S. Patents 1,089,096 and 1,201,899; in Canadian Patent 173,040, of Nov. 7, 1916, and in British Patent 10,500, of April 28, 1914.

EDWARD RAY WEIDLEIN

Mixed Orientation Developed in Crystals of Ductile Metals by Plastic Deformation

The Hull Method of X-Ray Crystal Analysis Answers This Contentious Question in a Positive Manner—Cold-Work Produces Change in Orientation Within the Original Grains

BY EDGAR C. BAIN AND ZAY JEFFRIES

IN EXPLAINING the mechanism of slip by which plastic deformation of a metal proceeds, Tammann¹ offers only two modes of motion, translation and twinning. Lehman² has pointed out that movement is possible by fluid flow in crystals, but metallographists and physicists are in general agreement that plastic deformation in metals results from some form of block movement of crystal fragments along slip planes. Since the mechanical twin bears certain fixed relations to the parent crystal, it cannot be said to give any evidence of general rotation or change in orientation. In terms of our modern conception of atomic structure, these earlier assumptions mean that in general parallel atomic planes of atoms during deformation remain constantly parallel to the positions in which they were in the original grain. As regards the geometry of even quite drastic deformation this is theoretically quite possible. Howe³ aptly

ing pits even after severe deformation. Howe³ to a great extent seems to corroborate this impression. "The regularity of the etching pits in each grain even after extreme plastic deformation and the sharp change in their direction from grain to grain are very cogent evidence of the retention of substantial uniformity of orientation during deformation."

One of the present authors,⁴ however, while granting the general truth of the regularity of etching pits in cold-worked metals, believes that the methods of determination of the regularity of direction in etching pits are not sufficiently accurate to warrant more than a qualified statement of the tendency and points out that the pits are usually examined in sections which are most likely to show minimum alteration of orientation. Yet cold-worked metals recrystallize on proper annealing, and "no explanation of the recrystallization of cold deformed metals on annealing has been forthcoming which did not assume a change in orientation within the initial grains due to the deformation."

FIG. 1. DIAGRAM OF SLIP IN CRYSTAL BLOCKS BY TRANSLATION AND ROTATION

likens this sort of plastic deformation to the motion of the compass needle in the skater's pocket, which is vectorial or translatory, even though the skater's gyrations are rotary. Fig. 1 diagrams a few crystal blocks slipped by translation and by rotation.

Matthewson and Phillips⁴ criticise this view of Tammann and fail to understand a rearrangement and reorganization of a deformed grain after annealing unless its fragments, enveloped by amorphous layers, have been differently oriented. They maintain that if Tammann's opinion were correct, then annealing would simply stabilize the grain in its altered position. Carpenter and Elam⁵ are inclined to hold to the view that no new orientations are produced in a grain during deformation. To quote: "There is no evidence known to the authors that after deformation the orientation of a crystal differs in any way throughout its extent." They base their conclusion upon the regularity of etch-

To sum up then, there is a disagreement as to whether or not deformation is accompanied by rotation and production of new orientations.

The authors have employed a new method of examination which offers a complete answer to the question of rotation during deformation. *If a very coarse grained specimen of metal containing only a few grains develops a complete assortment of orientations upon deformation by rolling alone, it would be positive proof of rotation of crystal fragments during deformation. This the authors have demonstrated conclusively.*

It was pointed out by Bain⁸ that the Hull pattern produced by the X-ray spectrometer was quite distinctive for different orders of grain size. A very coarse-grained specimen may show only one or two broad dashes on the film—indeed conceivably none at all—while with refinement of grain size the dashes decrease in size and increase in number. With very fine grain size the general pattern is produced on the film with smooth bands having even gradations on the edges.

For these experiments very coarse grained ingots of copper and aluminum were used. Fig. 2 shows a typical vertical section through the cast metal. This grain structure was developed by slow cooling. Specimens about $\frac{3}{8} \times \frac{1}{8} \times 1\frac{1}{2}$ in. were cut from the large ingots by a milling cutter. Great care was used to prevent deep strains. The specimens were polished and etched twice to remove superficial distorted metal from the surfaces. The separate grains were easily traced through the specimen, and usually numbered three or four. Such was the starting material.

Specimens thus prepared gave films of which Fig. 3 is typical. The film corroborates our idea of few orientations. Next, moderate cold-work was done upon the

FIG. 7. WEDGE-SHAPED TENSILE RUPTURE CHARACTERISTIC OF SINGLE-GRAIN SECTIONS OF DUCTILE METALS

specimens by rolling to one-fourth or one-fifth their original thickness, and the original grains, much elongated, were revealed by etching. Spectrograms of this rolled metal were similar to Fig. 4, indicating some new orientations, even though the rays struck only about one-fifth the former area. (The beam of X-rays strikes upon the same surface area of the metal after elongation as before deformation. Hence the opportunity for encountering different orientations is only a fraction as great as in the cast specimen.)

But when reduced to one-eighth original thickness, in the case of aluminum, and one-fifteenth, in the case of copper, the full patterns shown in Fig. 5 were yielded by the X-ray spectrometer. These patterns are characteristic of an extremely fine grained metal, with a very complete assortment of orientations at random, such as obtained from the finest powders.⁹

These cold-worked specimens were annealed to produce recrystallization and again placed in the spectrometers. The resulting films shown in Fig. 6 are characteristic of a material whose grains are perhaps 0.005 or 0.010 in. in diameter. There are not sufficient grains in the orientations for reflection to give continuous bands, and we may infer that there is a great reduction in number of orientations by the annealing.

The directional properties of single grains were strongly brought out in observations incidental to these experiments. Sykes¹⁰ observed single grain sections of

⁹It is true that one line of the face-centered patterns is virtually absent from these films, but it is a very weak one at best and offers no ground for denying chaotic orientation in the specimen.

molybdenum wire to give wedge-shaped rupture ends in tensile strength above 300 deg. C. This has been found true for both copper and aluminum at ordinary temperature. Two views of a broken test-piece of copper are shown in Fig. 7. The single grains may be seen faintly etched on the specimen. During the test each grain deformed in its own particular manner; some were much more depressed than others, the boundary offering greatest resistance to deformation.

In rolling such material, however, the directional tendencies of the grains were most clearly seen. Some shifted to the right, some to the left; some elongated, some widened. This led the authors to press a specimen of large grains between lead plates. The different grains were thrown into bold relief but the boundaries seemed always to resist compression most strongly.

After observing the directions of favored slip in a grain the question naturally arises, "Along what atomic planes does slip preferably take place?" If it be the planes of widest separation, then for copper and aluminum it will occur along the planes designated 1-1-1 by Miller indices, of which there are four systems in any grain. For iron the greatest spacing is between successive 1-1-0 planes, of which there are six in any grain. This inference seems to be correct, judging from X-ray spectrometry, although Howe mentions the 2-1-1 planes in this connection. Experiments are under way in the authors' laboratory to show these favored slip planes conclusively.

A striking evidence of the development of mixed orientations by cold-work is seen in Fig. 8, in which is shown at 300 diameters a unicast tungsten wire twisted cold several turns. The specimen, prepared and photographed by P. P. Tarasov, Cleveland Wire Division, National Lamp Works, was polished and etched along a longitudinal section through the axis. According to Howe, etching is most vigorous when progressing normal to the 1-1-1 plane. In this case we seem to have a change of orientation every 90 deg. of turn.

The continuity of deformation is clearly seen here. The steps by which slip takes place must be quite small, and, most important, fairly regular. The lighter-etched areas the authors believe are the cube faces (1-0-0 planes). Such a specimen as this would in all probability give an X-ray film showing all orientations present. In fact the method described above has been applied to coarse-grained tungsten ingot and wire produced from it, with the same results.

Studies in Colorado Shale Oils—B*

Secondary Oils Obtained From a Representative Colorado Shale Oil by Successive Distillations at Atmospheric Pressure—Character and Composition of These Decomposition Products and of Their Parent Material

By ARTHUR J. FRANKS

ALTHOUGH the work done thus far on the study of Colorado shale oils, as described by the author in this magazine,¹⁰ is of a preliminary character and cannot be expected to yield information that is entirely specific nor data which are in themselves sufficient for the deduction of many very definite conclusions, it does bring to light a number of prominent phenomena which are of considerable interest as well as importance. One cannot study the curves (Figs. 1 to 4, pp. 732-733) as a whole without observing certain persistent relationships and drawing therefrom a number of conclusions, some of which may be vague and merely suggestive, while others are quite definite.

The outstanding combination of phenomena met thus far is that of an increase in saturation, lowering of vapor temperature and specific gravity, loss of nitrogen and sulphur and the formation of coke and gas that accompanies a cracking distillation of the crude oil and its heavy distillates. The various losses as well as saturation increases are presented in Table III (p. 734). All calculations are based on a 1,000-c.c. sample of the original crude oil. The coke and gas losses are

total increase in saturation, and total losses of nitrogen and sulphur during the four distillations is well illustrated by the curves in Fig. 5.

LOSS IN SULPHUR AND NITROGEN DURING SUCCESSIVE DISTILLATIONS

From the calculations in Table III and the curves it is evident that most of the decomposition, loss of sulphur and nitrogen and increase in saturation occurs in the first two distillations. More than three-fourths of the nitrogen loss but only about 40 per cent of the sulphur loss occurs in the first distillation. In the second distillation only about 11 per cent of the total nitrogen loss but about 25 per cent of the sulphur loss occurred. Hence there does not seem to be any constant relationship between the amounts of sulphur and nitrogen lost during the decomposition of the more unstable material. Consequently the results indicate that the nitrogen and sulphur in these very unstable oils are present in more than one class of compound. The character of the losses suggests that this easily decomposed unsaturated material is probably made up of very heavy nitrogen compounds, sulphur compounds and those containing both nitrogen and sulphur.

The nitrogen and sulphur losses in the third distillation are small and practically the same. This suggests that the more stable, heavy oils that decompose contain both nitrogen and sulphur. However, it is practically impossible to obtain any definite information from the behavior of the oils on distillation and the losses, because there is now no doubt that there is a recombination of these elements, as the analyses of the new oils show. Hence the actual amount of decomposition cannot be exactly measured. The losses are merely a measure of the difference between the total amounts recovered and those originally present. Therefore but little further information is available through a continuation of the present methods of investigation.

The losses of sulphur and nitrogen in the fourth distillation are less than those found in previous ones. They tell nothing more than that the sulphur and nitrogen compounds present in the distillates after four distillations are very stable. Continued distillations under the same conditions would probably effect neither greater nor less decomposition of these substances than that observed in the last distillation. A study of all other losses during the four distillations shows that what is true of the nitrogen and sulphur compounds is true of any other unstable constituents present in the oil.

INCREASE IN SATURATION OF DISTILLATES DURING SUCCESSIVE DISTILLATIONS

The calculations for increase in saturation must dispel any doubts as to whether new saturated hydrocarbons are formed by the cracking of unstable material

FIG. 5. RELATION BETWEEN LOSS IN WEIGHT, INCREASE IN SATURATION AND LOSSES OF NITROGEN AND SULPHUR

expressed in percentages by weight of the crude. The sulphur and nitrogen losses are given in percentages of their respective total weights present in the crude oil. The loss in volume is expressed in percentages of that of the original oil. The increase in saturation is given in cubic centimeters in one case and in percentages by volume of the original saturation in the other. The relationship between the total loss in weight and the

*For Part A of this article see CHEM. & MET. ENG., vol. 25, No. 16, 1921, p. 731.

¹⁰CHEM. & MET. ENG., March 30, July 13 and Oct. 19, 1921.

in the heavy oils and prove that the increase is not merely due to a loss of unsaturated substances which would, of course, tend to produce the same result. For this reason the difference between the percentage saturation of the crude oil and that of the distillate is not a true measure of the saturated compounds formed during the distillation. Hence the actual volume of new saturated hydrocarbons was calculated in c.c., and is the sum of 100 times the products of percentage saturation and volume of each fraction. About 70 per cent of the total new saturated compounds formed were produced during the first distillation, and at the expense of only 44 per cent the total loss in weight and volume. In the second distillation only about 25 per cent were produced at the expense of about 28 per cent of the weight loss and 25 per cent of the volume loss. In the third distillation but 7.5 per cent were formed at the expense of 19 per cent of the weight loss and 20.7 per cent of the volume loss. In the fourth distillation there was no longer an increase but a loss of 3 per cent of the total saturated compounds formed, at the expense of 8.7 per cent of the weight loss and 9.8 per cent of the volume loss. Hence there is no constant ratio between the loss in weight and the increase in saturation.

There is a definite relationship, however, in which the total amount of saturated compounds formed varies with the loss in weight of oil according to a constantly decreasing ratio. This relationship is well illustrated by the curve in Fig. 5, in which the total increase of saturated compounds (in c.c.) is plotted against the total percentage loss in weight of oil. The maximum saturation is shown very clearly, as well as the fact that further distillations would result in a marked decomposition of the saturated compounds. It is very important to know that the saturation cannot be increased indefinitely by distillations at atmospheric pressure and that the limit is reached after the third distillation. Since the first of these distillations was made with the aid of hydrogen, it is very probable that the limit would be reached practically by two ordinary, destructive distillations.

FORMATION OF SECONDARY PRODUCTS DURING DISTILLATION

In order to secure more information as to the extent of decomposition and light oil formation and the general character of the cracked oils, the data in Table II (p. 733) were obtained. Since there can no longer be any question that *D* is a secondary product not present in the crude oil and that it is a part of the distillate formed during the cracking of the heavy residue *B*, all the compounds present in *D* must also have been thus produced.

The analysis of *D* brings to light some rather surprising facts. It contains 49.2 per cent of saturated hydrocarbons, 2.8 per cent of aromatics, 12 per cent of organic bases and 38.8 per cent of unsaturated compounds, most of which are olefines, because the other unsaturated compounds seldom amount to more than 1 or 2 per cent. Hence this secondary oil contains more saturated hydrocarbons and less olefines than *A*, a primary distillate that boils within the same temperature range and has practically the same specific gravity. The saturated portion of *D* contains 6.0 per cent of aromatics. The remainder must be composed almost entirely of paraffins, because its aniline point is

over 70 deg. C. The only other saturated hydrocarbons which could be present are alicyclics, or naphthenes. They cannot have been present in very great amount; otherwise the aniline point could not have been so high as the one determined. Chavanne and Simon¹¹ have shown that paraffins may be differentiated from naphthenes by the temperature above which they are completely miscible with aniline. This temperature is about 70 deg. C. for paraffins and about 30 to 50 deg. C. for naphthenes. Hence the above conclusion is the only logical one.

PERCENTAGE OF DECOMPOSITION DURING SUCCESSIVE DISTILLATIONS

The lighter secondary oil (*D*) contains about 50 per cent of saturated hydrocarbons and about 50 per cent of other compounds. It is also known that *D* amounts to 10.8 per cent of the original oil, or 17.4 per cent of the oils in *B* that are not saturated, and that *D* was formed at the expense of 20.8 per cent of the volume of this material. This accounts for a decomposition of 38.2 per cent of the labile portion of *B* by a single distillation, since the volume of oil lost plus the volume of oil recovered should be equal to the total volume of oil decomposed, assuming that no intermolecular changes such as polymerization or depolymerization occurred. The increase in saturation of *E* over *B* is 54 c.c., which means that 54 c.c. of the new saturated compounds in *E* was formed by the cracking of *B*. Hence *E* also contains a large amount of secondary products, all of which cannot be exactly determined. But since the cracking produced about equal amounts of saturated and other oils in *D* and since the amount of secondary unsaturated and basic substances in the heavy oils is at least equal to or more than that of the saturated hydrocarbons, it may be safely assumed that at least 54 c.c. of oil other than that which was saturated was produced at the same time, or a total of at least 108 c.c. Hence the sum of all the secondary products recovered and the oil lost amounts, in a single distillation, to a minimum of 55.7 per cent of the labile and unsaturated oils in *B*. But since the ratio between the saturated and other compounds in the heavy fractions of the secondary oils is probably nearer to 1:2 or 1:3 than 1:1 (according to the saturation for the distillates from the fourth distillation above 276 deg., and assuming the theory to be correct that the greater part of these distillates is new oil), it is more probable that closer to 65 or 70 per cent of the labile oils decomposed during the one distillation. This indicates, therefore, that at least 44 and perhaps as much as 50 to 60 per cent of the distillates (aside from the original saturated compounds) produced from *B* and found in *C* are entirely new oils and were not present in the crude.

If the same calculations are made for the oils for the fourth of the first series of distillations, the decomposition will be found to have been about 70 to 85 per cent of the unsaturated and basic heavy oils. Hence the new oils produced from that material form at least 57 and probably as much as 85 per cent of the oils from the fourth distillation.

That the extent of the decomposition is at least as great as has been indicated may be confirmed convincingly by a further study of the nitrogen and sulphur losses. Since the total loss of nitrogen by four

¹¹Comptes rend., vol. 168, pp. 1111, 1324; vol. 169, pp. 185, 285 (1919)

distillations was 7.65 g., the weight recovered in the secondary oils (to 276 deg.) only 1.96 g. and the weight in the undistilled crude (above 276 deg.) 15.68 g., then the total decomposition of nitrogen compounds was at least 61.3 per cent. If the amount of nitrogen in the secondary products above 276 deg. could have been determined, it would have raised the amount of decomposition to probably 80 or 85 per cent of the nitrogen compounds in the crude above 276 deg., because most of the nitrogen is in the heavy oils, whereas only that in the lighter portion could be determined with certainty. The total sulphur loss was at the same time 1.91 g., the known amount recovered 1.02 g. and that in the undistilled crude 4.64 g. Hence the decomposition of sulphur compounds amounted to a minimum of 63.1 per cent of those present in the original residue of the crude oil above 276 deg. Although these percentages are perhaps not exact, due to the fact that all the compounds of either nitrogen or sulphur may not contain the same number of nitrogen or sulphur atoms, they represent averages which are sufficiently accurate for the present considerations and help to confirm the calculations made in the preceding paragraph and the conclusions drawn therefrom.

VERIFYING THE PRODUCTION OF SECONDARY OILS BY VARYING THE DISTILLATION PROCEDURE

Since it is very important as well as interesting to know conclusively whether the distillates from the heavy oils are actually new products and whether the decomposition is as great as the results thus far attained indicate, another sample of *B* was distilled in a somewhat different manner than before. The purpose was to distill until cracking commenced, separate the primary distillate, and subject the remainder to a slow distillation in order to crack as much of the labile material as possible in a single operation without attacking appreciable quantities of the saturated hydrocarbons. The secondary oils could then be separated at the temperature at which cracking began. Since they would be almost free from the primary oils, a clearer view would be obtained of the extent of the decomposition and the changes produced in the unstable substances.

A 300-c.c. portion of *B* was distilled as before with a few exceptions. A shorter condenser was used, and it was held in a vertical position. A short, tubular separatory funnel was attached, by means of a two-hole rubber stopper, to the end of the condenser tube to serve as a gas trap so that the distillate could be drawn off as desired without permitting the escape of gas formed during the distillation. A T-tube, placed in the other hole in the stopper and closed at one end with a piece of rubber tubing and a pinch cock, conveyed the gas to bottles, where certain constituents could be removed. It also served as a safety device to prevent the sucking back of liquid from the bottles. The first bottle contained a saturated solution of copper sulphate acidified with 10 per cent of sulphuric acid. This solution absorbed the hydrogen sulphide and ammonia. A second bottle contained a solution of silver chloride in ammonia, which was used to absorb any acetylene that might have been produced. The gas then passed into a large test tube surrounded by cold water and containing 10 c.c. of bromine and 4 c.c. of water, to absorb ethylene and its gaseous homologues. The levels of the liquids in the various containers were so

adjusted as to produce a pressure of only about 2 cm. of water in the distillation flask.

The pinch cock was not closed until the air was expelled from the flask. The distillation was continued to 320 deg., when a slow but steady stream of gas began to bubble through the liquids in the bottles. This showed that cracking began in earnest at this temperature, although bubbles appeared at irregular intervals before 300 deg. All the distillate was now permitted to run out of the trap and into a graduate, where it was measured. It was labeled "*A'*," and preserved for analysis.

The rest of the distillation was made at a slower rate (one drop every two seconds) until there was no further increase in the amount of condensate. The trap was again drained and the oils measured. This cracked distillate was called "*C'*." A portion was withdrawn

TABLE IV. DATA FROM DISTILLATION OF *B*.

Distillate	Per Cent Yield	Sp. Gr.	Per Cent Sat.	Total Sat. C. c.	Weight, G.
<i>A'</i>	23.3	0.892	32.4	75	208
<i>B'</i>	46.7	0.978	1.1	5	457
<i>C'</i>	33.1	0.882	39.1	129	292
<i>D'</i>	19.8	0.848	47.4	94	168
<i>E'</i>	13.3	0.932	26.9	35	124

Total weight loss: 18.2 per cent of original oil (or 35.3 per cent of *B'*)

Loss in volume.....	13.6 per cent of original oil.
Volume of new oils in <i>D'</i>	19.8 per cent of original oil.
Volume of new saturates in <i>E'</i>	3.0 per cent of original oil.
Volume of other new oils in <i>E'</i>	8.4 per cent of original oil.

Total volume of oil decomposed.....	44.8 per cent of original oil.
Original volume of basic and unsaturated oils in <i>B'</i>	46.2 per cent of original oil.
Total decomposition of unsaturated and basic oils in <i>B'</i>	97 per cent
Secondary, or new oils in <i>C'</i>	94 per cent

for analysis and the remainder distilled in the usual manner. The oils which came over up to 320 deg. C. were separated, measured and labeled as "*D'*." The residue above 320 deg. C. was called "*E'*." The data from the distillation, together with analyses and calculations, appear in Table IV. The temperature curves for the distillation appear in Fig. 1 (p. 732). The wash liquors will be considered later.

PRODUCTION OF SECONDARY OILS VERIFIED

The results in Table IV furnish incontrovertible evidence of the truth of previous calculations and deductions and of the theory that the very heavy oils decompose almost completely into new products. It is also conclusively proved that these unstable and unsaturated and basic oils are the actual source of the saturated hydrocarbons in the secondary distillates. There can be no doubt that *D'*, which is 60 per cent of *C'*, is a new oil not present in the crude. The same is true of the 3.0 per cent of saturated compounds in *E'*. The 8.4 per cent of the remaining secondary oils in *E'* were calculated from the ratio between the new saturates and the unsaturated portion of *E'*. Hence it was here assumed that all of *B'* decomposed, with the exception of saturates; which seems to be the very question for which proof is being sought. However, the assumption was made for only a minor portion of the distillate. It is justified here because the decomposition amounts to 85 per cent, even if the ratio is assumed to be 1:1, which must be greater than the true ratio, because the latter decreases with increase in the boiling point of the oil and is 1:1 for the oils below 254 deg. Even with a decomposition of 85 per cent of the labile oils of *B'* the ratio is about 1:2.4, which makes the secondary unsaturated oils in *E'* amount to 7.2 per cent. Hence the assumption cannot be very far from the truth. In either case the final results—

namely, 97 per cent for the amount of decomposition of the unstable oils above 320 deg. and 94 per cent for the quantity of new secondary oils in this distillate—are sufficiently exact for present considerations.

The above experiments also establish the fact that there is no appreciable cracking of the oils boiling below 320 deg. when they are distilled at atmospheric pressure (which is about 615 mm. in Golden). Decomposition begins in earnest at about that temperature and becomes more and more pronounced as the temperature rises. The temperature of the oil necessary to give a vapor temperature of 320 deg. varies, of course, with the rate of distillation and the size and shape of flask used, but was about 375 to 380 deg. in this case.

It may be mentioned here that the unstable bitumens contain oxygen in small amounts, in addition to sulphur and nitrogen. This is shown by the fact that tiny drops of water have always been found in the secondary oils. The water was, of course, formed by the cracking of compounds which contain oxygen and hydrogen.

From what has already been said there can be no further doubt that the heavy fractions of crude Colorado shale oils are unstable, unsaturated, contain sulphur, nitrogen and oxygen, that they are largely decomposed by two or three ordinary distillations (or a single slow one) at atmospheric pressure and with a loss of much nitrogen and sulphur into much more stable products of simpler composition, lower specific gravity and higher saturation, and that the lighter of these products (below 276 deg.) consist mainly of paraffins, olefines and nitrogen bases with some aromatics, diolefines and compounds of sulphur and nitrogen.

MECHANISM OF THE REACTIONS DURING DISTILLATION AT ATMOSPHERIC PRESSURE

Since the nature of the labile material is very complex and the products of its decomposition so numerous, it is very difficult to advance a satisfactory explanation or even a comprehensive hypothesis for the mechanism of the reactions that must have occurred. Considering that the loss in weight is more than 35 per cent of the unstable oils and that some aromatics and nitrogen bases were formed, it seems that a rather complete disintegration of the heavy molecules took place with a subsequent recombination of some of their parts, rather than a mere splitting-off of certain atoms or groups so as to leave the main, catenary or nuclear structure. Perhaps both kinds of decomposition occurred. In any case, the resulting products should be of a more stable character, such as that actually observed. Hence the formation of saturated and stable compounds from unsaturated and labile substances is not only possible but reasonable, in spite of the fact that the cracking of petroleum gives products of a lower saturation.¹² The diverse results are merely due to the inherent differences in the parent material. As a matter of fact, energy and thermochemical considerations would lead one to expect that the more unsaturated and unstable the oil the more readily should it decompose into products of greater stability. The results of cracking heavy fractions of shale oils are, therefore, in harmony with modern theory.

It was hoped that some of the data might serve to throw a little light on the reactions which occur during the cracking of the unstable oils. For this reason

attempts were made to separate ethylenes and acetylene from the gases. Since the gas contained much hydrogen sulphide and some of it went over into the silver solution, it was necessary to redissolve the precipitate in strong HCl and pass the gas through three bottles of acid copper sulphate solution, one of sodium hydroxide and then into a fresh ammonical silver chloride solution. No precipitate was observed in this solution; hence no acetylene was present in the gas.

Since about 10 c.c. of bromides were formed, the gases must have contained olefines. A satisfactory fractionation of such a small amount of liquid was, of course, not possible. However, the series of boiling points observed during two rough fractionations showed the presence of bromides of ethylene, propylene and butylene and other heavier bromides which decomposed during the distillation at atmospheric pressure. The presence of these compounds was roughly confirmed by specific gravity determinations on three fractions.

The fact that much of the gas was not absorbed by any of the solutions used shows that it probably contained hydrogen and members of the methane series.

The presence of ethylenes in the gas indicates that a rather severe decomposition might have occurred. The presence of aromatics in the distillates confirms this deduction. Yet the absence of acetylene in the gas suggests that the aromatics were formed by a splitting of heavy polycyclic molecules, or heavy aromatic derivatives, rather than by a polymerization of acetylene. But then there is also the possibility that the acetylene either polymerized completely or combined with some other unsaturated hydrocarbon and consequently would not be found in the gas. It is obvious, therefore, that the evidence from these experiments is far too meager to serve as a basis for any intelligent considerations. Since the author does not desire to indulge in any mere speculations, a decision of the question must be left for further investigation.

NATURE OF THE COLORADO SHALE OILS

In concluding the discussion of results from this work the author wishes to make a few remarks concerning the nature of the crude shale oils, their distillates and the organic material in the shale which is the base of these products. It is already well known that true Colorado oil shales actually contain no oil, since only insignificant amounts of organic matter can be extracted with solvents. A destructive distillation is necessary before oil can be obtained. Therefore the oil is, of course, different from the parent substance. It has also been established that the less the decomposition of this material during the carbonization of the shale the more unsaturated and unstable, and the heavier is the oil.¹³ This is evident from the fact that oils of this character are produced when steam and inert gases, such as hydrogen, are used to minimize cracking, and because only the oils which have suffered extensive cracking are at all stable, saturated and contain many of the lighter constituents. The questions are then: Where do the light, saturated and stable oils of the crude originate? Are they entirely secondary products from the decomposition of the oil, or primary products of the carbonization of the "kerogen," or organic material in the shale? Are all the saturated hydrocarbons produced by secondary reactions, or does the original kerogen contain some of them? Since the oil is more and more unsaturated as it is produced with

¹²Rittman and Twomey, *J. Ind. Eng. Chem.*, vol. 8, p. 20 (1916).

¹³Botkin, *CHEM. & MET. ENG.*, vol. 24, p. 876 (1921).

less and less decomposition, there seems to be no doubt that the kerogen itself is very unsaturated. It is the writer's opinion that the substance which yields the saturated oils contains no saturated compounds whatever. If that is the case, then the latter were all produced by secondary reactions.

THEORY OF THE FORMATION OF OIL FROM SHALES

The next question which arises is: If saturated hydrocarbons are produced only by secondary decompositions, what is the nature of the primary products and how were they formed? If we consider the results reported in the preceding pages, the answer seems evident. The primary products are, or are similar to, those heavy, unstable fractions of the crude oil which decompose during distillation. They represent that portion of the organic matter in the shale which distilled over without cracking on account of the lowering of the vapor pressure in the retort by the presence of lighter constituents and gas produced during the cracking of some of the primary oil. The presence of such large amounts of this primary bitumen in the crude oil might easily be accounted for by slow rates of the cracking reactions, and hence incomplete equilibrium under the conditions of retorting.

But these heavy primary oils are soluble in the usual organic solvents, such as carbon bisulphide, ether, benzene and the like. The original kerogen of the shale is almost insoluble. If it is assumed that this unstable material has the same or similar composition as the kerogen, how can this difference in solubility be explained? In the writer's opinion, the transformation from insoluble to soluble substances might easily be accounted for by a depolymerization, or some similar reaction, in which the complexity of the very heavy molecules is reduced without a change in composition. Results of this kind have been observed by Engler and Lederer.¹⁴ Further research on this theory is necessary.¹⁵

On the basis of the evidence and considerations presented herein a quite satisfactory theory can be formulated to explain the formation of oil from shales of the Colorado type and the manner in which lighter and more saturated products can be obtained by cracking distillates of this crude oil. The carbonization of the shale must occur in two stages: (1) A depolymerization of the organic matter, or kerogen, to complex, heavy, unsaturated and unstable oils which do not distill at atmospheric pressure without decomposition; and (2) a cracking of this primary material into simpler oils of lower molecular weight, greater stability and containing up to about 50 per cent of saturated hydrocarbons. When the decomposition is only partial the result is an oil similar to the ordinary crude oils from Colorado shales. Complete decomposition of the primary oil yields a product similar to the distillate from the fourth distillation, or *C'*. By varying the conditions that exist during the retorting of the shale, oils may be obtained which vary from products which are practically entirely primary to those which are completely secondary. Hence careful control of physical conditions is of importance in commercial operations.

¹⁴Engler-Höfer, "Das Erdöl," vol. 1, p. 30 (1913).

¹⁵Since this paper was written an article has appeared by R. H. McKee and E. E. Lyder (*J. Ind. Eng. Chem.*, vol. 13, pp. 613 and 678), who have recently investigated the thermal decomposition of oil shales. Their conclusions are in accord with those presented in the present contribution. The theory is much strengthened by the fact that our conclusions were arrived at by different methods of investigation.

SUMMARY

1. The changes produced in a Colorado shale oil by successive distillations at atmospheric pressure have been investigated through a study of the specific gravities, vapor temperatures, saturation, sulphur and nitrogen in 10 per cent fractions. The light fractions are very stable and are not altered to any appreciable extent by redistillations. The heavy fractions are unstable and decompose easily. Most of the decomposition occurs during the first distillation.

2. Each decomposition is attended by the following phenomena: (a) The formation of gas; (b) a decrease in the weight and volume of oil recovered; (c) an increasing stability of the distillates; (d) a lowering of the specific gravity; (e) a loss of sulphur; (f) a loss of nitrogen, and (g) an increase in the amount of saturated hydrocarbons in the distillate. After the third distillation has been made the total volume of saturated compounds begins to diminish.

3. The light and middle fractions of the crude oil are very stable. Although decomposition commences when the vapor temperature is about 300 deg. C., it is not appreciable until about 320 deg. is reached.

4. It has been proved that new saturated hydrocarbons are formed during cracking distillations of crude oils and that the heavy, unsaturated bitumens in the oil (boiling above about 320 deg.) are the source of these saturated compounds.

5. The lighter secondary product (boiling below 276 deg.) consists mainly of paraffins and olefines, together with lesser amounts of organic nitrogen bases, aromatics, diolefines, and compounds of sulphur and nitrogen. It is quite similar, therefore, to the primary light oil which is found in the crude products.

6. The heavy, unstable bitumens in the crude oil have been shown to be very complex substances which contain sulphur, nitrogen (in large quantities) and oxygen, but practically no saturated hydrocarbons.

Evidence has been presented which supports the theory that these unstable compounds are merely intermediate products of the carbonization of oil shales. They decompose easily, and practically completely, when subjected to destructive distillation at atmospheric pressure, yielding the stable, secondary products.

7. A theory has been presented to explain the formation of oil from Colorado shales. According to this theory, heat first effects a depolymerization (or some similar transformation) of the kerogen to less complex, heavy, unstable and unsaturated compounds which resemble that fraction of the crude oil which boils above 320 deg. These labile oils then decompose to a varying degree, with the formation of simpler, stable products. It is this secondary decomposition which accounts for the presence of the light constituents in crude oils.

ACKNOWLEDGMENT

The author takes this opportunity to express his appreciation of the assistance rendered by C. P. Hackett, who made the distillations and most of the analyses recorded in this paper. Thanks are also due to J. P. Bacca, who made a number of the sulphur determinations. The valuable criticisms and suggestions of Dr. Victor C. Alderson and Prof. A. H. Low were of great aid in the preparation of the manuscript, and are acknowledged with pleasure.

Influence of Mass in Heat-Treatment*

BY E. J. JANITZKY

Metallurgical Engineer, Illinois Steel Co., South Works

IT IS well known that the mass of a piece of steel which has been heat-treated greatly influences the physical properties of the steel, but very little has been done to ascertain whether the law of the relation between the mass and the physical properties can be mathematically determined. With this idea in mind, the writer has prepared the following paper, the object of which is to point out that such a law exists and that it can be mathematically determined.

In the *Journal of the American Steel Treating Society*, Vol. 1, No. 1, October, 1918, I wrote an article under the heading, "Mathematical Discussion of the Influence of Mass on Heat-Treating," showing that the product of the surface per pound of steel (S) and diameter or thickness (D) is respectively $S \times D = 7.062$ (for plates), 14.125 (for rounds) and 21.185 (for spheres), these constants being in the ratio 1:2:3. The equation $S \times D = C$ represents a hyperbola in which the asymptotes are rectangular.

Not having any actual data at hand at that time, it was decided to search for some which would define somewhat closer than heretofore the mathematical relationships which exist in regard to this question. In October, 1920, the report of the British Engineering Standards Association was published and it was in this report, No. 75, that the writer found some very reliable data affording an excellent opportunity for this study.

The analysis of one of the steels tested in the British investigation was as follows:

C	Mn	S	P	Si	Ni	Cr	W	V
0.45	0.78	0.02	0.025	0.32	Nil	Nil	Nil	Nil

The accompanying test results were obtained from bars of this steel rolled to $3\frac{1}{4}$ in., $2\frac{3}{8}$ in., $1\frac{1}{2}$ in. and $\frac{7}{8}$ in. diameter respectively, and machined to 3 in., $2\frac{1}{2}$ in., $1\frac{1}{2}$ in. and $\frac{1}{2}$ in. diameter respectively. The bars were heat-treated before machining to test-piece dimensions.

The figures in Tables I and II used in this discussion are considered by the British committee as representing the true physical properties of the steel after the specified heat-treatment had been carried out. In this work there were four investigators, one of whom was the manufacturer of the steel; each checked his results in triplicate. The results of the investigators agree very closely on this steel and therefore are considered as representing within experimental error the true

properties of metal of this analysis. It should be kept in mind that the results of these tests represent the physical qualities of the center portions of the rounds and thereby avoid any harmful effects which could be ascribed to the steep gradient of the hardness penetration which exists near the surface. The rolled bars were cut to standard lengths for tensile and Izod tests, the length of the tensile test-bar being 6 in. and that of the Izod $8\frac{1}{4}$ in. In the case of the 1-in. and $\frac{7}{8}$ -in. round rolled bars, the tensile test-pieces were cut 9 in. long, in order to afford a better grip for the testing machine; in cases where very great hardness was expected after heat-treatment, the tensile pieces of the larger diameters were cut 10 in. long. After being cut, all the test-bars were centered in an automatic centering machine in order to get the test-pieces machined truly parallel with the cores of the test-bars.

FIGS. 1 AND 2. BRINELL HARDNESS IN FUNCTION OF SECTION AND HEAT-TREATMENT

Fig. 1—Water-quenched. Fig. 2—Oil-quenched. The unbroken lines were plotted from data given by the British Engineering Standards Association for samples, analyzing C 0.45, Mn 0.78, P 0.025, S 0.02, Si 0.32, and using the formula $B = \frac{nC}{D-d} + b$.

The Brinell impressions on the fractured tensile tests were made upon flat surfaces produced by milling down the shoulder on a screwed end of each specimen to the level of the cylindrical test portion. Only Brinell numbers of the tensile test-pieces are given in this discussion, as they represent the actual hardnesses of the centers of the test-pieces and are geometrically identical.

Using Brinell numbers as ordinates and diameters of the quenched sections as abscissas, two sets of curves were plotted from the British figures as shown in Figs. 1 and 2. The Brinell hardness of any section is in direct ratio to the surface per lb. of steel: $B = nS$, n being a factor which is constant for each steel of a particular analysis. The equation for round bars $S \times D = 14.125$ can thus be written $B \times D = 14.125n$.

This last equation is a true one, but in its present form is unsuitable for our purpose, inasmuch as it does not take into consideration the asymptotes of the curves. It can be seen that the axes of the rectangular system of co-ordinates are not the asymptotes of the curves. The equation changed to take into account the asymptotes reads

$$(B - b) \times (D - d) = 14.125n; \text{ hence}$$

$$B = \frac{14.125n}{(D - d)} + b \quad (1)$$

B is the Brinell hardness of any section desired; n is

*A paper presented before the Indianapolis meeting of the American Society for Steel Treating, Sept. 23, 1921.

a factor which is constant for each steel of a particular analysis, and which appears to be the square of the hardening capacity; D is the diameter of a section; b stands for the horizontal asymptote, which for this steel corresponds to a Brinell hardness of 175; d corresponds to the vertical asymptote of the hyperbola and whose value obtained from equation 1 is

$$d = D - \frac{14.125n}{(B-b)} \quad (2)$$

The maximum hardness of this steel was taken to be that of an $\frac{1}{8}$ -in. section quenched in water, which gave a Brinell hardness of 555. Thus the ratio is $555 \div 175$, or 3.17. Now $3.17^2 = 10$. Therefore for 0.45 carbon steel, $n = 10$.

With the discussion as it now stands, the following six curves are considered individually and their equations developed.

(1) 0.45 carbon steel quenched in water at 870 deg., C., and not tempered. From the British experiment, a $\frac{1}{8}$ -in. round section of this steel quenched in water at 870 deg. C. and not tempered had a Brinell hardness of 555. Therefore, substituting in equation 2, using the value 555 for B and $\frac{1}{8}$ for D , there is obtained for d , the vertical asymptote, the value 0.317. Thus the formula for this curve is

$$B = \frac{(14.125) \times 10}{(D - 0.317)} + 175$$

Using this formula, the values for the Brinell hardnesses of other sections quenched in water at 870 deg. C. and not tempered are given in Table III-A.

(2) 0.45 carbon steel quenched in water at 870 deg. C. and tempered at 500 deg. C.

From the British experiment, B is 311 and D is $\frac{1}{8}$ in. Substituting these values in equation 2, $d = -0.352$. The formula for this steel quenched as indicated and drawn at 500 deg. C. is $B = \frac{(14.125) \times 10}{D - (-0.352)} + 175$ and the Brinell hardness of other sections is given in Table III-B.

(3) 0.45 carbon steel quenched in water at 870 deg. C. and tempered at 600 deg. C.

From the British experiment, B is 255 and D is $\frac{1}{8}$. Substituting in 2, $d = -1.072$. Therefore, the formula for this steel quenched as indicated and drawn at 600

deg. C. is $B = \frac{(14.125) \times 10}{D - (-1.072)} + 175$. Table III-C gives the hardness of other sections.

TABLE III. HARDNESS OF 0.45 C STEEL, QUENCHED IN WATER AT 870 DEG. C (See Fig. 1)

$\frac{1}{4}$	321	277	235	359	272	239
$\frac{3}{8}$	255	241	217	253	230	219
$\frac{1}{2}$	241	229	212	228	216	210

TABLE IV. HARDNESS OF 0.45 C STEEL, QUENCHED IN OIL AT 870 DEG. C (See Fig. 2)

Dia. of Section, In.	— Brinell Hardness From — British Report			Brinell Hardness Computed by Formula		
	D	E	F	D	E	F
	Not Tempered	Tempered at 500 Deg. C.	Tempered at 600 Deg. C.	Not Tempered	Tempered at 500 Deg. C.	Tempered at 600 Deg. C.
$\frac{1}{8}$	255	255	229	256	256	229
$\frac{1}{4}$	241	248	223	239	239	221
$\frac{3}{8}$	228	228	207	219	219	210
$\frac{1}{2}$	217	217	202	210	210	204

(4) 0.45 carbon steel quenched in oil at 870 deg. C. and not tempered.

From the British experiment, B is 255 and D is $\frac{1}{8}$. Substituting in 2, $d = -1.072$. Therefore, the formula for this steel quenched in oil as indicated and not tem-

pered is $B = \frac{(14.125) \times 10}{D - (-1.072)} + 175$. Using this formula,

the Brinell hardness of other sections quenched in oil and not tempered are given in Table IV-D.

(5) 0.45 carbon steel quenched in oil at 870 deg. C. and tempered at 500 deg. C.

From the British figures, B is 255 and D is $\frac{1}{8}$. Substituting in 2, $d = -1.072$. Therefore, the formula for this steel quenched in oil as indicated and drawn

at 500 deg. C. is $B = \frac{(14.125) \times 10}{D - (-1.072)} + 175$, and the

Brinell hardness of other sections is given in Table IV-E.

(6) 0.45 carbon steel quenched in oil at 870 deg. C. and drawn at 600 deg. C.

From the British figures, B is 229 and D is $\frac{1}{8}$. Substituting in 2, $d = -1.947$. The formula for this steel

is $B = \frac{(14.125) \times 10}{D - (-1.947)} + 175$. Table IV-F gives the

hardness of other sections.

From the foregoing calculations it is apparent that the factors which control d in any carbon steel are the drasticity of the quenching medium and the extent of

FIG. 3. PHYSICAL PROPERTIES OF 0.45 C STEEL, WATER-QUENCHED FROM 870 DEG. C., NOT TEMPERED

Plotted from data given by the British Engineering Standards Association.

the tempering operation. As the drasticity of the quench becomes less and as the degree of the tempering becomes greater, the vertical asymptote d moves toward the left into the second quadrant of the system of co-ordinates.

It is interesting to compare the Brinell curve with the curves of other physical properties, such as tensile strength, elastic limit, elongation and reduction of area. This has been done in Fig. 3 and shows a similar hyperbolic tendency of these curves. The Brinell and tensile curves run parallel, as is to be expected.

The figures given in this paper speak for themselves, and point to the possibility of mathematically predicting results which are to be expected in different sizes of heat-treated steel.

The author wishes hereby to express his appreciation for the aid rendered by his assistant, H. Blumberg, in the preparation of this paper.

Science and the Coming Agriculture*

Our Future National Strength Depends on Scientific Study of Soil Fertility—Weakness of Eastern Nations Directly Attributed to Lack of Fertilizer for Food Crops—Methods of Estimating Requirements—Definite Problems to Be Solved by the Chemist

BY CHARLES H. MACDOWELL

President, Armour Fertilizer Works, Chicago, Ill.

THE efficiency of individuals and nations depends on an ample supply of food, clothing, fuel and transportation, and a study of these subjects and their relation to the future of man's welfare is always interesting. History records the fact that the decline and fall of the Roman Empire was due to the decline of crop yields and the failure of agriculture. Rome poured out the fertility of her suburban lands through the great sewer—into the sea; after that she poured out the fertility of Italy into the sea; and later she poured into the sea the fertility of Europe, or so much of it as she could amass under her own control. The constant growth of population was accompanied by a corresponding decline of yield per capita and yield per acre. The prices of food products rose higher and higher and the poorer classes ate less and less and poorer and poorer food, and thus the vitality of proud Rome dwindled away. When the Vandals and the Goths made their way into the northern part of Italy, they did not find the sturdy Roman soldier of the fifth century before the Christian era, but an underfed, anæmic people with weak bodies, and the once glorious Rome perished with only a faint voice.

UNDERNOURISHED RACES DECLINE IN ORIENT

The Oriental nations have developed populations out of proportion to the productive power of their soils, and their peoples are no longer efficiently fed. King estimates that there are provinces in China with a population of 3,480 per square mile, or an average of 240 persons, twenty-four donkeys and twenty-four pigs to every 40-acre farm—a small farm for even a single family in our own country. Whatever has been the unwritten history of China's ancient agriculture, she has in modern time exhausted every possible means to intensify production. Every canal channel, every available portion of her river courses, every sewer in the province—all are periodically scraped for every ounce of plant food to renew the producing power of the soil. The Chinese farmer is efficient. His methods are not scientific, but they are based on centuries of observation and experience. He uses practically no commercial fertilizer, and the soils in most of the fertile sections are out of balance—that is, they do not have the proper proportion of the various plant food elements to grow maximum crops. The nation as a whole has lost much of the individual initiative and lives a life of procrastination and vacillation. The people lack organizing ability in the larger sense and have little interest in outside affairs. Food in China is consumed dangerously near the point of production and drought and storms or other destructive agencies over even

small areas bring on great suffering and loss of life. Much the same condition exists in India. The Chinese and Indians possess common characteristics, and it is because they both as nations have reached the final stage of agriculture.

Japan, with a slightly better system of transportation and a larger knowledge of scientific methods, manages to feed her people fairly well. Japan has a population of 2,349 per square mile, or more than three to the acre of her cultivated lands. She has practically exhausted her cultivable area and must expand in foreign countries if her population is to increase. In her efforts to maintain her soil fertility, she saves and returns to the land 1.75 tons of human excrement per acre annually for each cultivated acre in the kingdom. To this is added mud, animal waste and decaying vegetable matter to the value of \$5 per acre. In this way the country reaches its maximum production all the time in order to maintain human life.

No data are available as to the calories consumed daily by the Chinese and the Indians. The Japanese dietary standard for a man performing ordinary muscular work totals 2,380 calories. It is estimated that the well-to-do class in the larger cities consumes 2,388 calories; that the coast region and middle classes in general consume 2,528 calories; and that the rural classes consume 2,002 calories. Rice supplies about half of the calories consumed; beef, fish, milk, greens, potatoes and pickled and dried radishes the remainder. It may be estimated that the ratio of these foods varies from a normal amount of meat, milk and fish in the best families to an almost exclusive diet of rice in the poorer rural sections, and the effect of this can be seen in the looks, stature and activities of the various classes of the people in the various strata of society. Very little meat is eaten in the Orient, a fact which may have direct relation to the life and progress of the people, and also their stature. Japan produces little livestock, her total pounds per capita being 4.21, as against 163.3 lb. per capita in the United States. As an acre of land will produce only so many pounds of meat, the Mongolian races have for hundreds of years been specializing on human beings, and with only reasonable success, because too many are now being grazed per acre.

EUROPEAN NATIONS FERTILIZE LANDS

Western Europe set out to develop her agriculture on a different basis from the Orient. Germany, Austria, Belgium, France, Spain, Italy and the British Isles are densely populated as compared with the United States. With the great increase in urban population following the intensive industrial development during the last fifty years, and with the decreased emigration,

*Paper presented before the Chicago Section, A.C.S., Sept. 23, 1921.

the fields of western Europe have been called upon for much greater yields than was necessary before the coming of the towns and cities. In order to obtain the maximum production from their fields, these countries have made use of scientific research and its application to the greatest degree. Their farmers place great confidence in the recommendations of their agricultural experts, and as a consequence they make greater use of science in their farm operations. The principle on which they have developed their agriculture is "greater yield per acre and better crops and livestock." The United States up to a few years ago was developing almost too exclusively on the basis of greater production per man power, regardless of yields per acre. In this respect, Europe would maintain a larger population and feed and clothe them better.

UNITED STATES NOW WASTING FERTILITY

The following comparison places the United States at a disadvantage so far as agricultural efficiency is concerned. Although our country is fifteen times as large as Germany, we produce only the same amount of barley and not quite twice as much oats. Germany produces six times as many potatoes and twelve times as much rice. When the war broke out, Germany had 5,000,000 farms averaging 15 acres, and we had 6,340,000 farms averaging 138 acres. These German farms produced 40 per cent more wheat, rye, barley, oats and potatoes taken together than we produced. Within the last thirty years, Germany has increased her per-acre yield of rye from 15 to 29 bushels, while the United States increased only from 14 to 16; Germany increased her acre yield of wheat from 19 to 30 bushels, the United States from 13 to 15 bushels; Germany increased the yield of barley from 24 to 39 bushels, the United States from 24 to 24.3 bushels; Germany increased her acre yield of oats from 31 to 59 bushels, the United States from 28 to 30 bushels; Germany increased the yield of potatoes from 115 to 208 bushels; the United States from 98 to 100 bushels. Germany has an area equal to the three states Minnesota, Iowa and Missouri, and under normal conditions produces 88 per cent of her food requirements. With a population almost half as large as the population of the United States and with only one-fifteenth the land area, Germany shows an agricultural efficiency about six times that of the United States.

METHOD OF ESTIMATING

How is this scientific or efficiency farming measured? In trying to get an estimate on this point, one would naturally have to take into account such factors as improved preparation, tillage and cultivation, improved seed and breeds, and the new principle of increased soil fertility. The average yield of wheat in Belgium is 37 bushels per acre, and her average consumption of commercial fertilizers 270 lb. per acre. England, on account of her great industries and her limited farm area, is the great importing nation of the world. Yet her yield per acre of wheat is 33.4, as against our 14.8 bushels in the United States. England shows a yield of 29.1 rye, 43.5 oats, against a yield of 16.1 rye and 29.5 oats in the United States.

These higher yields in western Europe indicate a more intensive and scientific agriculture than we have been able to reach in the United States. We are at the present time on trial in our United States agri-

culture. We are either at a standstill or on the decline, so far as acre yield is concerned, in much of our area. With a sparse population and broad areas of uncultivated lands, a nation can choose between extensive and intensive agriculture, but with densely populated country there can be no choice. The intensive method must be followed. We of the United States have been a wasteful people. We have had too much land, and have moved on from state to state in search of the more fertile spots of land, and neglected to maintain the producing power of our conquered area. We have been practicing the soil-robbing method, and with the waste involved and with improved farm machinery our per capita production has exceeded that of Europe. This condition did not exist, however, when a large per cent of our population was still on farms.

BALANCE OF POPULATION AND FERTILITY

Large populations and low crop yields do not go together. In this country our population is rapidly growing and we must more fully utilize nature's stores in our future development. Our national tendency has been to drift from the farm to the towns and cities, because of the great competition of industry with agriculture. Whether agriculture can be maintained on a high acre yield basis with a minimum number of producers is one of the unanswered questions of modern times. Whether the greatest yield can be obtained with farm machinery and large operation we have not yet learned. But that less than 50 per cent of our population are producers is sufficient argument that we are not likely to drift toward the conditions of the Orient. We shall likely maintain our share of the world's industries, and shall be required, if we do this, to make a more efficient farming country. In a way our industries, commerce and transportation have grown more rapidly and more efficiently than our agriculture. These factors must be balanced before we can count ourselves safe for efficiency in a broad national way.

Our population is increasing and our lands at the same time are being depleted. Our ditches are all lined with the fertility of the farms they were dug to drain. From our rivers we lose annually 500,000,000 tons of fertility, thereby diminishing our fertility at a rapid rate. Our sewer pipes are taking from our farms 50,000,000 tons of fertility annually. The crops that are removed from the soil, never to get back to the fields in the form of manure or any other form, take from our farm lands 30,000,000 tons of our fertility annually. In the face of these undeniable facts, our population will be, according to Dr. Edward M. East, of Harvard, more than doubled by the year 2020. At the same time he shows that according to our present methods of agriculture and our present rates of food and clothing consumption 197,000,000 is our ultimate population limit. After that point has been reached, our production and consumption will be on an equilibrium, granting that we utilize every acre of available land for farming purposes, and use it all approximately as we use our farm lands at this time.

FOOD AND CLOTHING CROPS

Our sheep must be used for clothing, and our cotton fields can never yield their place to food crops. In fact, they must be made to grow bigger crops, and more acres must be planted to cotton, as our population reaches nearer and nearer to the ultimate saturation point.

Just what per cent of our farm lands is required to grow the world's clothing no one has figured out, but whatever it is it can never give way to food production. In the case of cotton and sheep, we are growing food and clothing in one, which argues for a degree of efficiency that may be hard to match in growing plants exclusively for clothing. An advancing civilization requires better shelter and clothing as well as food, and there can be no other source for these than our agriculture. These features other than foods are not luxuries, but indices of civilization. They are guides to the progressiveness of nations. To have these and a wholesome system of transportation and commerce means the maintaining of a ratio of populations for production and for other vocations. What these ratios will ultimately be no one can predict, but they must be maintained. If our own people have any claim of superiority at this time, it is because we are better fed and clothed than most of the other nations. In the race for supremacy we shall hold out longer for this reason. But to maintain our place we must turn our attention to some of the great problems of the soil. We must make greater use of these foods we consume by giving greater directive force to our production agencies.

TECHNICAL PROBLEMS INVOLVED

Let us then consider the scientific problems that lie before us. They can be solved only by the scientist. He may be a chemist, he may be a physicist, he may be an engineer. He must be a seeker of knowledge, he must spend his time in research. The basic problem is the ultimate maximum efficient production of food and clothing. The engineer has before him the salvaging of arid but potentially productive regions. He may have to control, conserve and portion out flood waters. He may have to resort to reforestation to control precipitation. We know the general results obtained by devastation of our forests—floods, with consequent erosion of surface fertility. Can our engineers develop a remedy? Granted that production can be obtained, the engineer still has one of the gravest of the problems before him—transportation. Production must seek the level of consumption. Transportation is the only means by which this can be effected and the costs are now in too many instances prohibitive. The engineer must research the operations of transportation, seeking to reduce the cost. The chemist has a field too in fuel efficiency or even synthetic fuels.

CHEMIST'S WORK, THE SOLUTION

The chemist's big agricultural problem is fertility. As a matter of fact very little is known as to the relative importance of the various elements of fertility. Is plant food more important than moisture? Will bacteria destroy soil toxins? We are still groping in the dark on soil fertility. We have data giving specific results of certain fertilizing experiments under one set of climatic conditions on a given crop and soil. But who has made any progress in determining why these results were obtained, or how can they be interpreted in connection with a different set of conditions?

True, our worries on plant food supplies seem to be largely over. For a time it seemed as if the supply of available nitrogen was rather definitely limited. In the past few years the progress made in the fixation of atmospheric nitrogen has opened up unlimited supplies of this element.

If we forget political and geographic boundaries, there is sufficient available potash now blocked out to supply the world for a long time to come. Undoubtedly new deposits will be discovered. The present industrial byproduct waste of available potash will be further studied and this product saved for agriculture. The vast supply of potash in our shales and feldspars and other igneous rocks will remain as a reserve supply in case other sources fail. The potash from these sources is available now at a cost. Probably our chemists will find new processes which will enable these insoluble sources of potash to equal or better foreign prices.

The reserve supply of phosphate seems to be adequate so far as any reasonable time element is concerned. However, before long it will be necessary to call on the immense deposits of Idaho and other Western states. The problem of transportation will again be before us. We have methods now for rendering the insoluble phosphates of lime available for plant food. They are reasonably efficient in so far as there is little waste of phosphoric acid, but they necessitate the use of an equal quantity of sulphuric acid and a 50 per cent dilution of the product. Here again transportation intervenes. The present freight cost precludes the use of any but the higher grade phosphate rocks. The chemist has before him the problem of rendering the phosphoric acid of these insoluble compounds available for plant food without necessitating the reduction of the plant food content so that excess transportation charges may be overcome. He will, in the near future, be called upon to develop processes for utilizing the lower grade phosphates and phosphatic limestones of Tennessee and Kentucky and even to work over the waste dumps of present-day running.

For a long time it has been considered that these three elements, nitrogen, phosphorus and potassium, were the only plant foods necessary to supply ordinary soil. Recent years have brought about some change in this belief. Certain crops seem to demand some other element that is ordinarily not abundant in all soils. For instance, only within the last few weeks it seems to have been proved definitely that the tobacco plant must have a certain amount of magnesia in its food supply in order that it may properly cure. It is claimed that the superexcellence of the Hawaiian pineapple is due to the manganese present in these soils. Are we then to believe that only these two plants are peculiarly susceptible to such conditions? Can we not safely assume that every plant has a similar necessity? Most of the experiment stations of the country are now studying the effect of sulphur, both elemental and in compounds, on various crops. Oregon has shown surprising results on legumes with sulphates. New Jersey applies elemental sulphur for reaction within the soil itself. What a research field is opened to the agriculturalist and to the chemist!

BALANCING FERTILITY

This further leads us to the question of the balanced ration for plants. We are told that a man at a desk needs so many calories per day, the ditch digger so many more, etc. Our physicians have shown us the effect of a properly balanced diet and the dangers of malnutrition. No doubt plants have the same problems. We can assume that plants properly fed will respond in the same general lines that properly fed animals do. They will be more resistant to attacks of insects and to disease. Furthermore, the main function of the

plants under consideration is to feed man, either directly or indirectly through meat producing animals. A plant not properly nourished cannot be expected to produce as wholesome food as one in perfect condition. A horse that breaks into the corn crib will eat until he founders; a plant offered too much of a single food will undoubtedly have the belly-ache. We hear nowadays a great deal of vitamins and various water or fat soluble unknowns. Truly they are unknowns. We know not what they are, or what produces them, yet they seem to be one of the most important factors in nutrition.

We have determined in a vague way that the biological life of a soil has a great deal to do with the fertility of that soil. We know that certain plants such as legumes will not thrive unless nitrifying bacteria are present. Is it not safe to assume that other plants may be as susceptible to the influence of other bacteria and fungi as are the legume family? Bacteria or other microscopic organisms necessary for one plant may be poisonous to another. We know that certain lower forms of life such as the paramecium abound in the soil and live on bacteria. We know certain bacteria are fatal to certain plants. Undoubtedly crop failures are sometimes due to bacteria and famine enters as a competitor to plague, both from bacteria.

CONCLUSION

We could go on almost without end pointing out the problems that confront the scientist. These problems must be solved if this country of ours is to maintain itself in the front rank or as the leader of the nations of the world. Our tendency has been recently to commercialize our science. Our agricultural science must be national, must be removed from politics and commercial influences. We must realize that as a nation we must get more from our soil. Our scientists must solve these vital questions in the near future or the coming generations will find their food supply restricted either as to quantity or variety to a point where degeneration of the race sets in and conditions similar to those now obtaining in the Orient will be in effect here.

The Chilean Iodine Industry

Iodine is a most important byproduct of the Chilean nitrate industry. While iodine is recovered from seaweed in Japan (which country relies solely for its requirements upon this source), and also to some extent in France, Scotland, Norway and the United States, by far the greatest quantity of the element is derived from nitrate of soda.

In Chile the iodine industry is controlled by an association known as the *Combinacion de Yodo*, having its domicile at Iquique, reports Wilfred G. Eyre, clerk in American consulate-general, London, England. This combination at present operates under public deed or contract entered into on April 18, 1894. At a special general meeting held at Iquique on March 28, 1918, this agreement was prolonged to March 31, 1921, and has since been again extended for a further period of three years.

The combination is controlled by a set of bylaws which are of a most comprehensive character, regulating the association in all its spheres of action. The objects of the combination, as set forth in its statutes, are:

- (a) To regulate the export of iodine.
- (b) To regulate the distribution of the quota of each associate in the sales of the combination.

(c) To arrange for the sale of the iodine belonging to the associates and for that purpose entering into consignment contracts.

(d) To enter into an agreement with producers of iodine in other countries for the sale and supply of the iodine necessary to meet consumption through the instrumentality of agents appointed for that purpose or in any other form which may be found convenient.

(e) To bring about in every possible way the consolidation of the combination, procuring the adhesion of new producers and the holders of the stock that later on present themselves; and especially

(f) To obtain an increase in the consumption of iodine by means of propaganda, by offering rewards for the best studies suggesting new uses for iodine or to inventors or to those who discover some new application for this article.

Individual members are prohibited from making, exporting, selling, transferring "or otherwise negotiating" iodine, either in Chile or in any foreign country, except as laid down by the bylaws.

DETERMINATION OF QUOTAS

Each nitrate establishment belonging to an associate of the combination and actually manufacturing nitrate has the right, even if not equipped for iodine manufacture, to a quota in the monthly sales of iodine. This quota is determined in a manner prescribed in the statutes, each producer having the privilege of selecting either of two methods—(a) by actual trial of the establishment's capacity for producing iodine under specified conditions for a period of 90 days, or (b) through the decision of experts.

The statutes also give the combination power to enter into a contract for periods not exceeding 5 years with a European firm for the consignment and sale of iodine on the basis of a 5 per cent commission on sales effected by the European agents.

Article 42 of the statutes provides that the associated manufacturers shall pay a contribution not exceeding 5 shillings per quintal of iodine sold to cover the expenses of administration, which will be collected from the associates according to each one's monthly quota. To increase or reduce the contribution requires the assent of 80 per cent of the total membership.

LONDON SUB-COMMITTEE

Article 54 provides for the setting up in London of a consultative body known as the iodine sub-committee. Five of the six members of this sub-committee must be persons interested in the nitrate industry and members of the iodine combination or directors or legal representatives of nitrate companies associated in the combination, and the sixth a representative of the consignees.

Any member of the sub-committee who ceases to have the necessary qualifications loses his right to membership.

No two members of the sub-committee can be elected from the the same firm or company.

Physical Properties of Pure Platinum

The chemical division of the Bureau of Standards, in co-operation with the heat and optical divisions, has developed methods of obtaining platinum and some of its alloys in a state of extraordinarily high purity. A very sensitive test for the purity of platinum is afforded by the measurement of its "fundamental coefficient"—that is, the mean change of resistance per degree Centigrade in the interval 0 deg. to 100 deg. C. Some measurements of the fundamental coefficient of this recently produced platinum wire have shown values as high as 0.003922. The highest hitherto recorded value of this coefficient was 0.003917.

Uranium Steels

A Discussion of the Microstructure of Steels Containing a Similar Percentage of Carbon and Increasing Percentages of Uranium—Brief Description of the Influence of Uranium as an Alloy in Structural and High-Speed Steels

By HUGH S. FOOTE

IN PEARLITIC ternary steels the special element may exist as (a) dissolved in the ferrite, forming with it a solid solution; (b) combined with carbon as a double carbide of iron and the special element, or as a mixture of the two carbides; (c) partly dissolved in the ferrite and partly combined with the carbon.

Hypo-eutectoid steels containing not more than 0.60 per cent uranium are normally pearlitic, but any increase in the uranium content over this limit produces a characteristic carbidic component which heat-tints in a manner similar to uranium carbide. Fig. 8 shows a eutectic or eutectoid of the carbidic constituent remaining in a steel analyzing C 0.48 per cent and U 4.14 per cent, after being quenched in water from 1,000 deg. C. It is found on analyzing the residue remaining after dissolving annealed pearlitic steels with not more than 0.60 per cent uranium in dilute sulphuric acid with the aid of a galvanic current that the uranium is combined with carbon. At present there is not sufficient evidence to warrant a positive statement in regard to whether the uranium forms a true double carbide or a mixture of the carbides of iron and uranium.

Uranium exerts little, if any, direct influence upon the critical or transformation points of steel up to a content of 2.0 per cent; over this percentage the Ar transformations are lowered and markedly suppressed even at normal rates of cooling. Steels having the lowered

transformations are characterized by a martensitic structure, while those having the points suppressed or nearly so exhibit the polyhedral structure of gamma iron and austenite.

The microstructure of pearlitic uranium steels with less than 0.60 per cent uranium shows that they resemble plain carbon steels except that the ferrite-cementite aggregate is finer. Fig. 1 shows a steel with C 0.74 per cent and U 0.36 per cent after annealing at 1,600 deg. F. and slowly cooling to room temperature. With further additions of uranium to about 1.0 per cent the pearlite is no longer lamellar, and a carbidic component is formed. Fig. 3 shows the microstructure of an annealed steel containing C 0.31 per cent and U 0.86 per cent; on quenching the steel is martensitic with the carbidic component rejected to the boundaries of the polyhedral grains. (See Fig. 4.) The microstructure developed by a steel with C 0.48 per cent and U 4.14 per cent, both in the annealed and quenched condition, is illustrated by Figs. 5 to 8. Increasing the uranium, C 0.46 per cent and U 6.97 per cent, produces both on slow cooling and quenching a polyhedral structure containing no traces of martensite; the carbidic component is eutectic in form and is also rejected to the grain boundaries. (See Figs. 9 and 10.) This steel shows also a marked suppression and lowering of the critical points, while an increase in the rate of cooling sup-

FIGS. 5 TO 8. STRUCTURE OF C 0.48, U 4.14 STEEL

Figs. 5 and 6. Annealed at 1,600 deg. F. $\times 150$ and $\times 1,000$ respectively. Etched with picric acid.

Figs. 7 and 8. Water quenched from 1,830 deg. F. $\times 150$ and $\times 1,200$ respectively. Etched with 1 per cent HCl and heat tinted.

pressed the points entirely and produced the same microstructure as quenching (Fig. 11). Likewise, increasing the temperature from which cooling commenced produced a marked weakening and suppression of the points and the steel became much harder than on cooling from lower temperatures. This may be explained as being due to the solution in the iron of a compound of iron, uranium and carbon at high temperature which did not have time to aggregate on cooling.

Dr. George K. Burgess, of the Bureau of Standards, states that unlike zirconium and titanium, uranium appears to enter into solid solution in steel—that is, it is a true alloying addition. In the normalized specimens a distinct martensitic and troostitic pattern is present, which undoubtedly is due to the presence of uranium in solid solution, as otherwise the structure would be found to consist of granular pearlite and ferrite.

Uranium steels when quenched sometimes contain microscopic white crystals as is shown in Fig. 2. The microscope shows also that (a) these crystals do not

heat-tint in the same manner as uranium carbide; (b) they are not found in annealed steels; (c) they are etched only by aqua regia; (d) in steels with a uranium content of more than 0.60 per cent uranium where the carbide component is formed, these crystals are found associated with the carbide constituent as is shown by Fig. 11. An explanation of the occurrence of these crystals is derived from the analysis of the residue of quenched steels that have been dissolved in dilute acid and aided by a galvanic current; the indications are that a double or complex carbide of iron and uranium is formed at high temperatures which dissociates or dissolves slowly and remains imbedded in the matrix as isolated, microscopic crystals. Examination of Fig. 8 also confirms the existence of two different crystallographic forms of the carbide component.

PHYSICAL PROPERTIES OF URANIUM STEELS

The most striking features of uranium as an alloy are, first, that it does not need to be augmented or intensified by the addition of other alloys, and secondly, the readiness with which uranium steels lend them-

FIGS. 9 TO 11. STRUCTURE OF C 0.46, U 6.97 STEEL

Fig. 9. Annealed from 1,770 deg. F. Etched with picric acid. $\times 70$.

Fig. 10. Annealed from 1,700 deg. F. Etched with H_2O_2 and NaOH. $\times 300$.

selves to a water-quench. Uranium increases the hardness and hardening power of steels by means of its ability to emphasize the characteristics of the cementite; the hardness imparted thereby is not accompanied by as great a degree of brittleness as that induced by other carbide-forming alloys.

Carbon-uranium steels are pre-eminently adapted for uses which necessitate a low drawing temperature, in that they possess under these conditions a remarkable combination of hardness, strength and ductility. The effect of the addition of small amounts of uranium on the physical properties may be ascertained by an examination of the following tests, made on different classes of steel and compared on a basis of like ductility:

Elastic Limit	Tensile Strength	El. 2 In. Per Cent	Red. Area Per Cent
Carbon 0.32 per cent, uranium 0.22 per cent: 154,800	162,800	15.5	59.3
Carbon 0.30 per cent, nickel, 3.50 per cent: 111,000	124,000	15.5	53.0
Carbon 0.30 per cent, chromium 0.95 per cent, vanadium 0.18 per cent: 146,200	162,700	15.0	57.0
Carbon 0.28 per cent, chromium 0.85 per cent, molybdenum 0.37 per cent: 154,000	165,000	15.0	58.5

In other words, the addition of a small amount of uranium imparts to steel a sufficient increase in elastic and tensile strengths to make it comparable to the more complex alloy steels.

SMALL HEATS UNRELIABLE

The system of making steels for test or research purposes in an electric furnace of about 400-lb. capacity was abandoned by the writer because of the many defects in the steel. Moreover, the furnace conditions were not easily controlled, with a result that the product was often such as to lead to erroneous conclusions. The test results that follow were made on steels from electric furnace heats of two tons or more each, and the results are representative of each particular type.

TYPE 628

Carbon 0.32 per cent, uranium 0.22 per cent, manganese 0.66 per cent, silicon 0.23 per cent

URANIUM-NICKEL STEELS

The combination of small amounts of uranium with nickel produces a type of steel in which the desirable features of each alloying element are magnified. The hardness on quenching is increased by the addition of uranium, thus producing a desirable quality in the case of parts that are to be subjected to wear. The effect of additions up to 0.60 per cent of uranium to pearlitic nickel steels is to decrease the grain size and to make the pearlite more sorbitic.

In general, uranium-nickel steels differ from pearlitic nickel steels in these essentials: (a) they have higher elastic limits for the same ductility; (b) they are harder than nickel steels when heat-treated; (c) they are more susceptible to heat-treatment—uranium-nickel steels harden considerably when cooled in air; (d) they possess superior dynamic toughness and resistance to fatigue when properly heat-treated.

URANIUM HIGH-SPEED STEELS

A metallographic study of uranium high-speed steels indicates that the uranium tends to promote the formation of complex carbides. The cutting efficiency and the property of "red hardness" of high-speed steels is wholly dependent upon complex carbides. According to Osmond, when steels of this type are heated to a high temperature, the carbides dissolve and change the composition of the gamma iron solid solution, by means of which the critical points are lowered. In other words, it is the increased amount of dissolved carbides which causes the end of the transformation to fall below ordinary temperatures, with the result of partial aus-

FIG. 12. VARIATION IN HARDNESS OF URANIUM-BEARING HIGH-SPEED STEEL AS DRAWING TEMPERATURE CHANGES

tenitization. The "secondary hardening" is due to the fact that when the partly austenitic steel is tempered, the dissolved carbides are slowly precipitated to a stage where the transformation is completed and the steel is martensitic. According to Scott,¹ the microscopic evidence is positive that the constituent which accompanies the appearance of "secondary hardening" is martensite.

A comparison between the microstructures of a uranium and a uranium-free high-speed steel annealed at the same temperature shows that steels containing uranium show in general a larger number of carbide globules than are found in uranium-free steels; in the

FIG. 13. VARIATION IN HARDNESS OF URANIUM-BEARING HIGH-SPEED STEEL AS QUENCHING TEMPERATURE CHANGES

hardened condition, both classes show practically the same amount of undissolved carbides. Since the complex uranium-carbide is apparently more soluble in gamma iron than those complex carbides ordinarily found in high-speed steels, it is reasonable to infer that uranium exerts an important influence on the property of "secondary hardness."

Curves are shown in Figs. 12 and 13 to illustrate the effect of different quenching and drawing temperatures on a uranium high-speed steel.

Method for Obtaining Color Value of Sugar Solutions

Many sugar solutions, such as molasses, contain so much coloring material that they are too dark to be read on color-measuring instruments even when the thickness of the layer used is decreased as much as is practicable. Dilution of such heavy, dark-colored solutions with water causes some change to take place, resulting in a flocculation and precipitation of a part of the coloring material which is present in the undiluted solution. This precipitated material is so fine that it does not settle and therefore renders the solution turbid. If this turbid solution is used to determine the color value of the original dark-colored solution, an error is caused by the dispersion or scattering of the light by the fine precipitated particles. If these particles, which are known scientifically as dispersoids, are filtered off and the remaining clear liquid used, an error is likewise made, since a part of the coloring matter which was originally present has now been removed.

A new method for the measurement of the color value of sugar solutions is being developed by the United States Bureau of Standards in which these errors are avoided. The method consists essentially in diluting the dark-colored solution in a concentrated sugar sirup of known color value. The dilution with water decreases the protective influence of sucrose, which acts as a protective colloid, while the dilution with concentrated granulated sirup maintains the same state of equilibrium and prevents the precipitation of the coloring material. Beer's law is valid only as long as flocculation and change in color value are prevented. If laboratory practice invalidates the law, truthful results cannot be obtained. This fact has been ignored by technical sugar chemists up to the present time. The basic principles of technical colorimetry stated by Stammer, long before the days of colloidal chemistry, have never been tested under more modern conditions.

Production of Asphalt Increases

The quantity of native asphalt and native bitumens sold in the United States in 1920 was 198,497 short tons, valued at \$1,213,908, according to the United States Geological Survey. This was an increase of 125 per cent in quantity and of about 78 per cent in value over 1919. Gilsonite was reported from Uinta County, Utah, wurtzilite (or elaterite) from Duchesne County, Utah, and grahamite from Pushmataha County, Okla.

The sales of manufactured asphalt obtained from domestic petroleum amounted to 700,496 short tons, valued at \$11,985,457, or \$17.11 a ton. Compared with 1919 these figures indicate an increase of 14 per cent in quantity and 37 per cent in value.

The sales of asphalt manufactured in the United States from Mexican petroleum in 1920 amounted to 1,045,779 short tons, valued at \$14,272,862, or \$13.65 a ton. This was an increase of 55 per cent in quantity and of 85 per cent in value over 1919.

Coal Production in France's Devastated Region

Considerable progress was made in the exploitation of the war-damaged coal mines of France during the first half of 1921. Altogether the mines in the Departments of the North and the Pas-de-Calais produced 7,344,000 tons of coal during the first six months of 1921, as against 3,534,000 tons in 1920. During the first half of 1913 they produced 14,946,000 tons.

Air Required in Baking Cores Made With Linseed Oil

Results of Laboratory and Plant Experiments on the Consumption of Air and Oxygen in Baking Linseed Oil-Bound Cores, Together With a Review of Available Data on the Absorption of Oxygen by Linseed Oil in Drying

BY A. A. GRUBB AND U. S. JAMISON*

THE ventilation of an electric core oven is a problem quite different from that of an oven using coal, coke, oil or gas as its source of heat. In the latter case the hot gases from the burning fuel are permitted to pass over the cores; these gases contain a large percentage of uncombined oxygen, so there is always present a great excess of oxygen over any quantity actually required in the baking process. The ventilation required to maintain proper combustion is always sufficient, too, to carry out of the oven any water vapor and other gases which may be formed.

But not so with the electric oven. No ventilation is required for operation of the heating elements, so any air passed through the oven is for the sole purpose of supplying oxygen and carrying off gases; further ventilation results only in loss of expensive heat energy.

Linseed oil differs from water-soluble binders in that its hardening in the core in the process of baking depends upon oxidation rather than merely losing moisture. Water is used in green core sand along with oil to improve the green bond properties and permit the sand to be packed closely enough that the oil can cement contact points together. In sands containing clay or other natural bond the water also serves to form a sort of plaster or semi-solution of this bonding material so that upon drying the grains of sand are cemented together.

The quantity of air which should be supplied to the baking cores is determined, then, by two factors: first, the moisture coming off the cores must be diluted or carried out of the oven, and second, sufficient oxygen must be supplied to oxidize the oil properly. It may be necessary to supply an excess of oxygen over that actually used; if so, how great an excess?

MOISTURE ELIMINATION

Green core sand contains on an average about 6 per cent of moisture. This is nearly all in the vapor form before the bake is half completed. A series of temperature readings made by means of a thermocouple point located in the center of a baking core show that the rise in temperature is retarded somewhat in the neighborhood of 212 deg. F., after which it again continues to rise at its former rate, indicating that the water has been vaporized. Each 100 lb. of green core sand contains about 6 lb. of water, which upon vaporizing expands to about 165 cu.ft. at 212 deg. F. and to still greater volumes at higher temperatures. The steam would thus drive practically all the air from the oven or at least dilute it to an extent that there would be insufficient oxygen for the bake were it not for the admission of fresh air through ventilating ports or openings about the doors. These considerations point to the necessity of introducing some air into the oven in

order to carry out the water vapor. Inasmuch as practically all the oxidation occurs during the latter half of the bake, the need for air is not imperative until after all the water has been vaporized and the temperature has risen pretty well toward maximum.

OXIDATION OF LINSEED OIL

Upon exposure to the air linseed oil absorbs oxygen and is converted into a tough or even hard varnish. Ordinarily this transformation is very slow, but it may be hastened by raising the temperature 300 or 400 deg.; higher temperatures are apt to cause at least partial decomposition.

According to Cloez¹ fresh linseed oil is composed as follows:

	Per Cent
Carbon.....	77.57
Hydrogen.....	11.33
Oxygen.....	11.10

When thoroughly dried he found that 100 g. of this oil had increased to 107 g. as follows:

	G.
Carbon.....	72.27
Hydrogen.....	10.57
Oxygen.....	24.16
Total.....	107.00

These figures indicate that in drying 100 g. of linseed oil, 5.3 g. of carbon and 0.76 g. of hydrogen are given off. Possibly these were given off in part as hydrocarbons, but it is more probable that they were oxidized to carbon dioxide and water. The figures also show that 13.06 g. of oxygen were absorbed and retained. If we assume that the carbon and hydrogen which were lost were oxidized to carbon dioxide and water, then the 5.3 g. of carbon would unite with 14.1 g. of oxygen to form 19.4 g. of carbon dioxide, and the 0.76 g. of hydrogen would unite with 6.08 g. of oxygen to form 6.84 g. of water. The complete drying of 100 g. of linseed oil would then require 33.24 g. of oxygen and would produce 19.4 g. of carbon dioxide. A. Genthe,² another investigator, found that in drying, linseed oil absorbed 23 per cent of oxygen. The work of these investigators, then, indicates that between 30 and 40 g. of oxygen is required to completely dry 100 g. of fresh linseed oil.

LABORATORY TESTS

A number of experiments were made to determine the quantity of air which should be supplied and the quantity of oxygen actually used in thoroughly baking linseed oil cores. A Vitrosil tube, 1 in. in diameter and 12 in. long with a 4-in. transparent section in the middle, was set up horizontally in such manner that it could be heated with bunsen burners. In the ends of

*Director of Laboratory and Chemist, respectively, Ohio Brass Co., Mansfield, Ohio.

¹Allen's Commercial Organic Analysis, vol. 2, p. 345.

²Ibid., vol. 2, p. 348.

the tube were placed rubber stoppers, one of which supported a thermometer so set that it showed the temperature in the middle of the tube. Air entering the tube was passed through a calcium chloride tube to insure dryness. Upon leaving at the other end of the vitrosil tube, the gases were drawn through another calcium chloride tube and a soda lime and caustic tube for carbon dioxide absorption. A calibrated water-bottle aspirator was used for drawing air through the train. The air which was received in the water bottle was analyzed for oxygen content by means of an Orsat gas apparatus. The difference between this value and 20.8 was taken as a measure of the oxygen used in baking the core.

The core sand used in the tests was one of the standard mixtures used in our core room. It consisted of 70 volumes of Michigan City lake sand, 30 volumes of sand-blast dust, 8 volumes of water and 2 volumes of raw linseed oil. According to weight such a mixture is 5.05 per cent water and 1.18 per cent linseed oil. The

* When two numbers for "Air Used" are given in the table, the upper one indicates the number of cc. air admitted or passed over the core while it was baking.

sand, water and oil were measured out accurately and mixed in a glass-stoppered salt bottle to prevent evaporation. The cores were made and baked in 3-in. nickel combustion boats. The boats were filled with green core sand, firmly pressed down and then stroked off even with the edges. This produced cores of uniform size. All the test-cores were baked for 45 minutes. When baked they were allowed to cool in a desiccator and were then tested for strength by resting them on two knife edge supports $1\frac{1}{4}$ in. apart and applying weight midway between the supports. Breaking strengths of less than 450 g. indicate cores that would be unsatisfactory for general foundry work on account of their fragility, while results over 600 g. indicate very strong substantial cores.

The accompanying table shows the results of eighteen tests, together with some of the calculated results. They are arranged in order according to the quantity of oxygen absorbed per gram of linseed oil in the core. In several of the experiments the tube was cooled as soon as the bake was complete and more air was then passed through to sweep the tube. The second number gives this total volume which was sampled for the oxygen determination. In addition to the tests recorded

in the table, two cores were baked in an atmosphere of carbon dioxide; they were of a grayish color and so weak that they could scarcely be supported on the fingers. Four cores were also baked in a large excess of air, the ends of the Vitrosil tube being left partly open; the average baking temperature was 393 deg. F. and the average breaking strength was 612 g.

DISCUSSION

While the results were not as uniform as might be desired, we believe they were as nearly so as could be expected from this sort of problem and this method of handling it. A survey of the figures shows the following points worthy of notice:

1. The nine strongest cores—Nos. 4, 5, 6, 8, 9, 10, 11, 12 and 14—were baked at an average temperature of 395 deg. F. They used 0.73 g. of oxygen per g. of linseed oil and broke under an average load of 609 g.

2. Nos. 1, 2 and 3 were baked at too high temperatures; the average was 493 deg. F. They used 1.36 g. of oxygen per g. of oil and broke under a load of 237 g.

3. Nos. 13, 15 and 17 were baked at too low temperatures; the average was 318 deg. F. They used only 0.38 g. of oxygen per g. of oil and broke under a load of 319 g.

4. Nos. 16 and 18 were baked at the proper temperature, but insufficient air and oxygen were supplied; the average baking temperature was 390 deg. F. They used only 0.30 g. of oxygen per g. of oil and broke under a load 297 g. Practically all the oxygen admitted to the cores was used.

5. Considering the nine strongest cores mentioned above, 5,341 c.c. of air supplied the oxygen for baking 76.2 g. of green core sand; this was in the ratio of 8.5 lb., or 112 cu.ft., of air at room temperature to each 100 lb. of core sand. Oxygen to the amount of 475 c.c. was absorbed; this was about 40 per cent of oxygen content of the air supplied to the cores.

6. No. 14 used 75 per cent of the oxygen supplied to it and produced a fairly strong core.

PLANT TESTS

An attempt was made to check the above results by tests in an electric core oven in our foundry core room. This oven had a volume of 350 cu.ft. and was equipped with a fan and ventilating device so arranged that the

TABLE II. TESTS ON LARGE CORE OVEN

Wt. of Cores, lb.	Time in Oven, Min.	Fan Recirculating, Min.	Fan Exhausting, Min.	Air Admitted to Cores, Lb.	Average Strength, Lb.
1 300	68	12	3	85	55
2 287	65	12	1	40	61
3 320	70	15	0	17	54
4 312	78	0	0	17	52
5 337	70	0	1	40	53

air in the oven could be recirculated or fresh air could be introduced from without, part of the exhaust passing up the flue. When the fan was operated, it was set to recirculate entirely or else to recirculate and introduce fresh air at the rate of about 300 cu.ft. per minute. This figure was determined by placing a Pitot tube draft gage in the exhaust flue. The temperature of the oven was controlled by a thermostat. Five bakes were made, varying the quantity of air introduced. In addition to the regular cores, twelve test briquets, similar in shape to those used in cement testing, were placed on each rack. The test-cores were made of the same mixture as the laboratory test. After baking, they were broken on a Wadsworth core-testing machine; a breaking strength of 40 lb. indicates a fair core, above

60 lb. a very strong one. Table II gives a summary of the results obtained.

In each case except No. 4 the fan was operated near the middle of the bake. This was done in order to clear the oven of water vapor and other gases. In No. 1 the fan exhausted for 1 minute about a quarter of an hour before the rack was removed. The figures on "Air Admitted to Cores" were calculated from the period the fan was exhausting and drawing in air, and the estimated air content of the oven was added in; hence these figures are very approximate.

Oxygen determinations were made on samples of air drawn from the oven during the latter part of bakes Nos. 1, 4 and 5. No. 1 gave values of 19.8 per cent and 18.0 per cent. No. 4 gave 11.3 per cent and 13.0 per cent. No. 5 gave 16.7 per cent, 14.1 per cent and 15.0 per cent.

DISCUSSION

The test-cores differed but little in strength—all were good. Evidently we were unable to cut down the air supply to a point where the strength of the cores was seriously affected. Ventilation served possibly to reduce the time of bake, but even in No. 4, with no fan ventilation, there was sufficient air in the oven or enough leaked in around the doors to produce good cores. According to the laboratory test, 300 lb. of cores should require about 2.5 lb. of oxygen. However, 17 lb. of fresh air contains only 3.9 lb. of oxygen, so either the "Air Admitted" figures given in the table are too low or the oxygen determinations are too high. It is very likely that more air than that recorded got into the oven, as there were rather loose fitting doors at both front and rear. Even when making allowance for these possible errors, it is evident that from 8 to 10 lb. of air, possibly less, supplies sufficient oxygen to bake properly 100 lb. of green core sand.

CONCLUSIONS

In order to bake linseed oil-bound cores properly, at least 1 lb. of oxygen should be supplied for each pound of linseed oil in the cores. This would require about 4.5 lb., or 60 cu.ft., of fresh air. Each 100 lb. of green cores should then have at least 5 lb., or 67 cu.ft., of air. These figures indicate only the minimum quantity required for oxidation purposes. It is well to change the air in an oven at least once after the moisture has been vaporized. Where fuel is cheap, greater excesses of air probably have no harmful effect and may be of advantage.

In the correct bake linseed oil uses about 0.73 per cent of its weight of oxygen. This figure is considerably higher than those given by Cloez and Genthe, referred to above, for oxygen used in drying linseed oil. We need not be surprised at this, because a properly baked core is more than dried. We have found in our core room that a linseed oil core shows a slight greenish tinge when merely dried out. When a brass casting is poured about such a core, a "core blow" is very apt to result and the core, instead of becoming very fragile and easy to remove, bakes hard in the casting. On the other hand, when baked to a decided brownish color, they can usually be knocked out of the castings without trouble.

These facts indicate that in core baking the oxidation process is carried beyond the drying stage; the oil is actually burned in a slight degree.

Legal Notes

BY WELLINGTON GUSTIN

The Conrad Patents, the Noiseless Gear. Using Bakelite Micarta, Void for Lack of Invention

The Conrad patents, No. 1,167,742 and No. 1,167,743 for a noiseless gear, the material of which is a composition of bakelite and fiber, known as "Bakelite Micarta," of which Conrad was not the inventor, have been held void for lack of invention in the United States District Court, Southern District of Ohio, by Judge Peck. (Westinghouse Electric & Manufacturing Co. vs. For-nica Insulating Co., 270 Fed., 632.)

The complainant sought to enjoin defendant from the manufacture and sale of blanks to be used in the making of gear wheels composed of a fibrous material with a phenolic condensation product for a binder, which was charged to be a contributory infringement of said Conrad patents as owned by it. The defense was that the patents were void for want of invention, or, if showing invention, because Conrad was not in fact the first inventor, and for want of novelty.

DESCRIPTION OF THE PATENT IN DISPUTE

The subject-matter of the patent was the non-metallic or noiseless gear. The object sought by the inventor was the production of a gear wheel which would be light, strong, durable, infusible and impervious to moisture and to most chemicals. To obtain this result, said the court, sheets of fibrous material, such as cloth or paper, are impregnated with an adhesive liquid material, preferably a phenolic condensation product, such as bakelite dried in an oven, laid together with the treated side of one to the untreated side of the next, hydraulically pressed under heat until the material is fully impregnated and firmly cemented into a hard, compact mass, and, after cooling, subjected to a baking process. The result obtained is a laminated fibrous material, capable of withstanding great heat, of high tensile strength, which can be turned and bored in the same manner as wood. The finished plates are then cut into gears in the usual way. As a modification metallic end plates or shrouds were placed on gears to protect the edges of the composite structure from injury and to give added strength.

The binding material, bakelite, is described as a condensation product of phenols and formaldehyde. Claim 7, which is typical of those relied on, states: "A gear having a self-sustaining working body portion, composed of fibrous material and a phenolic condensation product."

The complainant produced by the process a gear which was highly useful and commercially successful, but also superior in some adaptations to all preceding types of noiseless gears. The question presented to the court was, How much of this result can be attributed to the exercise of the inventive faculty of Conrad?

GEARS DESCRIBED IN BAEKELAND PATENT

The new element that made this success possible was a composition of bakelite and fiber, together known as "Bakelite Micarta." This material was admitted to be the production of Dr. L. H. Baekeland, covered by his patent No. 941,605. It is said that the same process of

building up the laminated material described in Conrad's patents is fully set forth by Dr. Baekeland in his composite cardboard patent of March 5, 1912, No. 1,019,406. On Dec. 16, 1910, Dr. Baekeland filed his application for a patent on a "machine element," meaning thereby gears, pulleys, etc. This application, filed 2½ years before that of Conrad, although not allowed until after Conrad's application had been filed, was considered in determining the question whether Conrad was the first inventor under the patents in suit. Baekeland described a gear made of a phenolic condensation product, either compounded with fiber, or built up with layers of wood, cardboard, paper, or similar porous material, and compressed between metal plates. This was to be done either with or without the use of interior metal strengthening plates. The gears were then to be cut from disks of the material so formed. He described such gears as capable of withstanding comparatively high temperature and of enduring conditions destructive to most plastic compositions, as being of great hardness, toughness and wearing qualities, and, as against metal gears, silent in operation. The difference between the two patents appears that in Baekeland the reinforcing plates are considered essential to the strength of the gear, while in Conrad they were considered optional with the gear maker.

WAS CONRAD'S ADVANCE PATENTABLE, ASKS THE COURT

Conrad knew the material as suitable for gears without reinforcement as well as with it. Baekeland's material was bakelite, fiber and metal; Conrad's was bakelite and fiber, with or without metal, as conditions might warrant. Conrad's advance was that the supporting metallic plates might, in cases, be omitted. Was this invention in a patentable sense, the court asks.

Bakelite Micarta is described as a hard, fibrous substance, strong, insoluble, infusible and resistant to water, oil and most chemicals. It was at the time of the application for patents in suit used mostly as an electric insulating material. Noiseless gears of rawhide, compressed fiber, or fabroil, and vulcanized or hard fiber were common. Rawhide and fabroil were compressed and held in shape by end plates. Hard fiber, on the other hand, was a self-sustaining material. It was composed of cotton-rag paper treated with chloride of zinc, which rendered it gelatinous and adhesive. The layers of material, having been so treated, were pressed together and formed a laminated, fibrous, self-sustaining, hard material, useful for gear making. The resemblance of Bakelite Micarta, the new material, to the hard fiber was striking. The difference was that the Micarta contained a new and better binding cement, and the process of its manufacture was not injurious to the fiber and left it unimpaired. The question arises, Was it after all anything more than an improved hard fiber?

Then if hard fiber had been familiarly utilized for the manufacture of noiseless gears for years, was it a patentable invention for Conrad to employ the greatly improved hard fiber, Micarta, which itself was not his invention, for the same purpose? The answer to this question determined the matter for the court.

The old hard fiber gears had been used with and without end plates and shrouds. Conrad described in his patent a gear made of Micarta without such supports, but did so as an alternative. In his claim he is careful to limit the use of the material to the "working body portion," thus covering a gear supported by end

plates, they not being the working body portion thereof. Therefore the court held that Conrad's effort was but the skillful selection of material rather than invention, and that both his patents were void.

Substitution of one material for another, which does not involve change of method nor develop novelty of use, even though it may result in a superior article, is not necessarily a patentable invention, says the court.

The bakelite gear was held to be an infringement of the compressed fiber or fabroil gear in the case of General Electric Co. vs. Continental Fiber Co., which the reader may find in vol. 256 of the *Federal Reporter*. It was here held by the Circuit Court of Appeals that the Miller patent for the use of compressed textile fabrics for gear manufacturing was fundamentally new and entitled to a broad range of equivalents. Its infringement was based on the ground that both depend upon the presence of a large number of fibers in a small space.

Condition in Offer Prevents Contract Agreement

In an action by the Atlantic Terra Cotta Co. against the Chesapeake Terra Cotta Co. (113 Atlantic, 156) plaintiff sought to recover damages for the wrongful repudiation of an alleged contract to accept and use certain terra cotta. A memorandum of the alleged agreement was made in writing and signed by both parties. The first condition of plaintiff's proposal was as follows: "(1) This proposal is good for thirty days from date, and acceptance thereof is subject to a form of contract satisfactory to us."

Now the court said that had this proposal been omitted from the written offer made by the plaintiff, the written acceptance of the defendant could have been held to constitute a valid contract, upon the ground that although neither the offer nor the acceptance contained any express intent as to the time of delivery or payment, yet in such case the absence of the ordinary stipulations as to time of delivery and time of payment would be supplied by implication of law. Where no time for delivery is fixed by such a contract, the law implies delivery within a reasonable time. Where no time of payment is fixed by such a contract, the law implies that the time of payment is upon the delivery of the goods.

WRITTEN CONDITION WAS ONE PRECEDENT TO CONTRACT

The essential question, therefore, was whether this cited condition was one precedent to the formation of a contract between the parties in reference to the offer that a formal written contract should be executed, and whether writing upon the offer that it was accepted did create a contract.

The Supreme Court of Errors of Connecticut in the case affirmed the judgment of the trial court that such acceptance of the offer did not create a binding contract, but said the completing of a contract depended upon later extension of a formal contract.

Further, this court says: "Where there is no written proposal or acceptance expressed to be subject to a formal contract, but there has been a reference to a written contract in the negotiations, then it becomes a question of fact whether the parties intended the agreement in a certain memorandum to constitute a contract or intended that there should be no contract until the execution of a formal written contract; and such intention is to be gathered from the language used when interpreted in the light of the attendant circumstances."

Non-Magnetic, Flame-, Acid- and Rust-Resisting Steel

New High Alloy Steels Developed in the Research Laboratory of the Crucible Steel Co. Which Can Easily Be Worked and Machined, but After Heat-Treatment Become Hard and Resistant to Attack of All Agencies

A SHORT NOTE on a "Highly Resistant Alloy Steel" appeared in CHEMICAL & METALLURGICAL ENGINEERING for Sept. 22, 1920 (vol. 23, p. 568), following the presentation of a paper on this subject before the American Society for Steel Treating, by Charles M. Johnson, director of research department, Crucible Steel Co. of America. This paper has been printed in full in the July 1, 1921, issue of that society's *Transactions*.

Several of these high-alloy steels were studied primarily in an effort to find a steel which could be forged, rolled or sheared in thicknesses down to 0.01 in., be machinable in the cold, yet offer maximum resistance to cutting flames. It was found that polished samples of sheet made from the experimental melts, when immersed twenty-four hours in various solutions, showed remarkable resistance to acid solution, as indicated in Table I.

These steels have therefore been called "Rezistal," and a certain amount of them placed on the market. When attacked by an oxyacetylene flame it takes twenty times as long to melt a hole through it as does ordinary steel. Exposed to oxidizing flame Rezistal is only slightly stained after several hours in a gas furnace at 1,100 deg. C. (2,000 deg. F.), indicating its utility for racks, clamps and other heat-treating fixtures. Tests for thirty minutes at 1,100 deg. C. are also included in Table I, + measuring gain in weight, — loss. Copper solutions, which plate out readily on high-chromium steel, will not deposit copper on grades 3 and 4. Rezistal will remain for days in Pittsburgh tap water, developing only the faintest traces of rust; it resists saturated H_2CO_3 even better. Paring knives from grade 2 will not stain in fruit juices, but furthermore do not stain the operators' fingers if the handles are made of wood or fiber.

Further tests by corroding agents follow:

Lead. A 1,200-g. crucible of No. 3 gained 0.43 g. after holding lead eight hours at 900 deg. C. (1,650 deg. F.). No scaling occurred on the outside.

Cyanide. Metallic samples were immersed one hour in NaCN at 1,000 deg. C. (1,850 deg. F.). Grade 3 lost 154 mg. per sq.in.; copper steel 482; wrought iron 478.

Concentrated Salt Solution. Slight tarnish after seventy-two hours.

Pasty Quick Lime. No change after 170 hours.

Neat Cement. No change after twenty-two days.

Concentrated Carbolic Acid. Trace of discoloration after ninety-two hours.

Oxalic Acid. Lost 1.41 mg. per sq.in. in ninety hours.

Hot Asphaltum. Slight discoloration suggesting an enamel after one hour.

Silver Nitrate. No effect, cold or hot.

Saturated Alum Solution. Slightly etched in spots after twenty-two hours.

Caustic Soda. No effect after three hours' boiling in 20 per cent solution.

Rancid Butter. No effect after eight days.

Sulphurous Acid. Quickly assumes dark protective coating, after which loses 0.3 mg. per sq.in. per day.

Mercuric Chloride. Bright and lustrous after 120 hours in cold (loss 0.45 mg. per sq.in.) or thirty minutes in boiling N 1000 solution (loss 2.1 mg.).

Lactic Acid. No effect after twenty-four hours in 0.2 or 1.0 per cent solution; loss in latter case 0.1 mg. per sq.in.

Gasolene. Slight brown tarnish after thirty days; loss 0.63 mg. per sq.in.

MAGNETIC PROPERTIES

Grades 2 and 3 are both non-magnetic in the rolled condition or after extended heat-treatments. The permeability with respect to air is 1.05, and the residual magnetism not greater than 4 lines per sq.cm. After prolonged heating at 700 deg. C. (1,300 deg. F.) a slightly greater attraction to a magnet was noticed, but this was lost by a short heat to 870 deg. C. (1,600 deg. F.). It is of interest to note in this connection that high-carbon manganese steel of the Hadfield type shows a similar slight increase of magnetic susceptibility at about 650 deg. C. (1,200 deg. F.), but more so at 595 deg. C. (1,100 deg. F.) after ten minutes' heating and also loses this increased susceptibility at about 815 deg. C. (1,100 deg. F.) after ten minutes. Cold work increases the magnetic susceptibility of grade 3 to a noticeable extent. To remove this, heat to 1,000 to 1,100 deg. C. (1,950 deg. F.) for a few minutes; cool in air and heat again if necessary.

Three grades of Rezistal were immersed in boiling liquid air for ten minutes together with a piece of ordinary sheet steel and a piece of 25 per cent nickel steel. The 25 per cent nickel steel showed strong magnetic susceptibility (about the same as ordinary steel), but after removing it from the boiling air this effect was entirely gone in one minute. The three grades of Rezistal were not attracted by the magnet immediately after removing from the liquid air or when still immersed.

It was also found that while the ordinary sheet steel on being taken out of the liquid air was very brittle and could be snapped off with a pair of pliers, the new alloys and also 25 per cent nickel steel were apparently as tough as ever, showing no indication of brittleness. Therefore Rezistal can be described as tough and strong in all temperatures from — 185 to + 1,300 deg. C.,

FIGS. 1 TO 5. TYPICAL MICROSTRUCTURE OF REZISTAL

Fig. 1. Ingot of grade 2. Brinell No. 179.
Fig. 2. Transverse section of sheet made from the same material as shown in Fig. 1.
Fig. 3. Hammered bar made from grade 2. Brinell number 228.

Fig. 4. Same as Fig. 3, after being held one month at approximately 900 deg. C. Brinell number 302.
Fig. 5. Grade 2, air-quenched after one hour at 1,100 deg. C. Brinell number 223.

which is a fairly good range. This ought to make very good material for bottles for transporting liquid air, as it did not become brittle at the lower temperatures.

PHYSICAL PROPERTIES

Figs. 1 to 5 show typical microstructures. Ingots show cored structure. Heat and work convert this into polyhedral crystals of a solid solution—sometimes laminated—which persists to high quenches, finally recrystallizing at about 400 deg. C. Quenching from five minutes at 1,300 deg. C. gives very coarse polyhedral grains with faint ghost-like markings suggesting the old location of bands of flattened crystals. The original paper gives many tests after various heat-treatments; from which the following in Table II have been selected to indicate what results can be had.

Modulus of elasticity of Rezistal is about 27,200,000 in tension and 11,700,000 in torsion. In 0.038-in. sheets (Brinell 244) it will stand three or four 90-deg. reverse bends, and can be bent flat around a pin four thicknesses in diameter without cracking. Various grades have impact strength of from 16 to 53 ft.-lb., being highest in specimens oil-quenched from 1,200 deg. C.

For machining, this steel should be heated at about 800 to 850 deg. C., held there until thoroughly heated and then allowed to cool to room temperature before it is taken out of the furnace. It can then be machined, drilled or milled with high-speed tools. For cutting to length, a friction saw running at high speed or a thin carborundum wheel can be used. The best method found so far is to use a thin metal slitting saw of

regular standard high-speed steel. This steel cannot be cut successfully with an ordinary hacksaw.

When annealing for cold-forming, the steel should be brought to a temperature of 1,150 to 1,200 deg. C. and

TABLE II. PHYSICAL PROPERTIES OF REZISTAL

Grade	State	Yield Point	Ultimate Strength	Elongation	Reduction in Area	Hardness (Brinell or Shore)

3-8	Water-quenched from 1,050 deg. C.....	78,700	120,700	45	45.7	40
3-8	Water-quenched from 1,200 deg. C.....	57,900	99,400	60	51.1	38
3-8	Air-cooled after 1 hr. at 1,300 deg. C.....	53,900	99,200	43.5	43.6	

held at this temperature for one-half hour in thicker sizes. In thin sheets it need not be held more than five or ten minutes; then turned over and held ten minutes more. It should then show a scleroscope hardness of 30.

This steel can be welded best with the oxyacetylene flame and a suitable flux, using a strip of the same material to fuse the edges together. The sand-blasted

or pickled sheets should weld the best; if scale be still on the sheets, it may interfere seriously with the welding. This material gives excellent welds on cast iron by the electrical welding method.

ESTABLISHED USES

Rails, racks and trays in enameling furnaces ranging from 1,600 to 1,800 deg. F. where ordinary steels scale heavily at these temperatures.

Valves and parts for internal combustion engines to resist high temperatures together with corrosive fumes.

Cooking utensils, such as pots, skillets, etc., that are to be kept bright.

Spatulas, paper cutters, trays in gas ranges that burn and rust readily when made of ordinary steel.

Vault plates and hinges that are to resist attack of oxy-acetylene flame and burglars' saws and drills.

Annealing and case-hardening boxes.

Flue dampers in furnace stacks.

Rivet-heating furnaces.

For instruments in all places where a steel is desired that is of the lowest magnetic susceptibility.

Containers for acetic acid and other corrosive organic acids.

Shafts for motor boats to resist sea water.

Paring knives for fruits and vegetables.

Rifle and shot gun barrels, stainless, non-rusting and non-corroding from ammunition.

Cast lead pots.

Cast cyanide pots.

Cast parts of rivet-heating furnaces.

Rust-resisting wire for umbrellas.

Wire of high electrical resistance (560 ohms per mil ft.).

Hardening trays for steel stamps.

PROPOSED USES

Boiler tubes—either water or fire tubes.

Boxes for safe deposit vaults.

Planes for aircraft, light and having great strength and ductility in thin sections for highly stressed parts.

Oil burners.

Tips for oxyacetylene cutting torches.

Roof gutters and conductors.

Check valves and valves of all kinds in steam lines.

Pipes and tanks for carrying commercial sulphuric and nitric acids at atmospheric temperatures.

Pipes for corrosive mine waters.

Pickling vats and rods for same.

Nails for resisting acids.

Hotel and kitchen cutlery, non-breakable, super-stainless, easily sharpened and requiring no heat-treatment by the cutlery manufacturer.

Saw-tooth bread and cake cutters.

Rust-resisting tapes.

Hot plates in laboratories, highly resistant to acid and heat attack.

Muffles for heat-treating furnaces operating at less than 1,100 deg. C. (2,000 deg. F.).

Hoods and running boards for automobiles.

Turbine blades.

Fertilizer pans.

Tubes for annealing needles.

Dies for die casting.

Pyrometer-protection tubes.

Valves and valve seats for steam traps.

Polished surfaces of flatirons.

Golfstick heads.

Hooks and wires for suspending parts to be hardened at high temperature, such as high-speed steel.

Perforated bottoms for tanners' tanks.

Art vases and statuettes.

Tunnels for manufacture of lamp black.

Wire spokes for automobiles, motorcycles, bicycles, etc.

Burial caskets.

Mine water pumps and machinery, highly resistant to cold sulphuric acid.

Castings for resistance to acetic, sulphuric and nitric acids at ordinary temperatures.

Castings to resist rusting at atmospheric temperatures and to resist scaling at temperatures up to 1,100 deg. C. (2,000 deg. F.).

Wire of great toughness and rust resistance, for mine cables and cables for incline planes.

Runners for ice boats.

Punties for polishing glass.

Rods for skimming brass.

Wire to stand red heat continuously in shoe machinery.

A Hardened Lead for Bearing Metal

IN DISCUSSING P. H. Brace's paper on Calcium¹ presented before the last meeting of the British Institute of Metals, R. T. Rolfe, a member, wrote that he was particularly interested in lead alloys containing calcium and other alkaline earth metals designed to replace ordinary tin-base alloys for bearing purposes.² This application apparently arose out of the war-time scarcity of tin. One of the proprietary alloys sold for this purpose which he had used experimentally for the lining of some main and connecting-rod bearings for a hot-bulb oil-engine gave on analysis the following results:

INGOT METAL AS RECEIVED

	Per Cent		Per Cent
Antimony	nil	Zinc	0.04
Arsenic	0.01	Magnesium	nil
Tin	nil	Barium	1.30
Copper	0.04	Calcium	0.79
Bismuth	nil	Lead	97.05
Aluminum	nil	Oxygen (difference)...	0.66
Iron	0.11		
Nickel	trace		100.00
Cobalt	nil		

This alloy was stated to contain "from 97 per cent to 98 per cent of lead, the balance being barium and calcium used as hardening elements," with which specification the analysis agreed very well.

A photomicrograph, magnified 150 diameters, of the alloy, etched with acid ferric chloride, is shown in Fig. 1, and depicts the hard spots of the intermetallic lead-alkali compound set in a lead matrix, the structure being thus typical of a normal bearing alloy.

The lead so hardened, which was manufactured by an electrolytic process, was certainly much harder than ordinary lead, as would be seen by the comparison below of the Shore and Brinell hardness figures of the two:

	Brinell Hardness Figures		Shore Hardness Figures	
	Load 500 Kg.	Load 1,000 Kg.	Ordinary Hammer	Magnifier Hammer
"Hardened" lead.....	31.2	26.5	7.5	13.5
Ordinary lead.....	8	(Unmeasurable)	2	3

Again, the "hardened lead," when struck by a hammer, emitted a distinct "steel-like" ring, in marked contrast with the note obtained from ordinary lead.

The alloy was stated to have been tested in properly

¹CHEM. & MET. ENG., vol. 25, p. 105 (July 20, 1921).

²Jour. Institute of Metals, vol. 25, p. 171.

FIG. 1. LEAD, ALLOYED WITH BARIUM AND CALCIUM. X 150. ETCHED WITH ACID FERRIC CHLORIDE

designed bearings up to a pressure of 6,000 lb. per sq.in., with satisfactory results.

Mr. Rolfe was not in a position to say how the bearings lined with this alloy compared in service with those lined with ordinary white metal of Admiralty composition. In the meantime there were several points which required consideration as regarded the possible replacement for bearing purposes of the ordinary white metals by such an alloy.

In melting this alloy there was an oxidation of the calcium and barium, much more dross being produced, particularly if any stirring was done, than with the tin-base alloys. The ultimate end would be that the hardening effect would disappear, the lead reverting to the ordinary variety. To avoid this, it was therefore advisable not to have a pot of the metal standing molten, but to melt down the required quantity at the moment it was to be used. It would appear that there was likely to be a certain amount of oxidation in the metal as manufactured, which would increase with remelting, some oxide being mechanically contained, the rest being rejected. It would be noted that, in the analysis of the metal first quoted, a deficiency of a little more than $\frac{1}{2}$ per cent, not found by a very careful search for any other possible metals, has therefore been described as "oxygen."

In lining the bearings referred to, a temperature of about 450 deg. C. was found to be the best at which to pour. It was necessary to have the mandrel fairly hot. If feeding was not properly done, a shrinkage cavity was left just below the point at which the metal was run in.

COST COMPARISONS

The alloy in question cost £100 per ton at a time when the cost of the white metal alloy of Admiralty composition (tin 85 per cent, copper 6.5 per cent, antimony 8.5 per cent) was £210 per ton. On the other hand, owing to the greater specific gravity of the lead alloy (11.04 against 7.20), the cost, volume for volume, became £167 for the lead alloy, as compared with £210 for a ton of Admiralty composition white metal. The "hardened lead" therefore showed a saving of about 20 per cent as compared with Admiralty white metal, but approached fairly closely in cost to some of the tin-base metals in which a proportion of lead was added, but which, however, were quite as satisfactory for general bearing purposes as the Admiralty alloy. For example, the alloy 70 per cent tin, 6 per cent antimony, 6 per cent copper and 18 per cent lead had been demonstrated by Mr. Rolfe to be as reliable in service as the other, while its cost would have been £180 as compared to £210 for the other.

"Hardened lead" was claimed to be a better bearing metal than tin-base alloys, although this appears doubtful. It would be seen, however, that there was no such advantage on the score of cost as might be expected from an alloy composed of about 98 per cent lead.

Permanency of hardness in this bearing alloy was said to be fully maintained after extended periods of use. The decrease in hardness up to 200 deg. C. was stated to be less than in the case of tin-base alloys.

There is at present no information on the relative corrodibility.

The writer would be much indebted to Mr. Brace if he could afford any further information, particularly as to the behavior of "hardened lead" bearings in serv-

ice, in, for example, high-speed inclosed engines, turbines, etc.

Mr. Brace also noted that alloys of this type had found successful application to crankshaft bearings in American automobile engines. Oxidation was so troublesome when casting thin sections that the Westinghouse company had not used these alloys to any extent. It found that whereas the Brinell hardness of freshly cast metal was about 12 (10 mm. ball, 500 kg. load) it increased to about 20 upon aging.

Regenerative Furnaces for Heat-Treating*

LIKE the thermally efficient gas or oil engine, the regenerative furnace has its limitations as well as its field of usefulness. It is an efficient type of furnace for releasing and utilizing heat from fuel, and is particularly suitable for the use of fuels, such as producer gas, which, by reason of chemical composition and low calorific intensity, will not produce high temperatures without regeneration.

The regenerative principle, by recovering a part of the sensible heat carried out of the heating chamber by the spent gases, and utilizing it to preheat the air or fuel, or both, permits a high hearth temperature and results in economy of fuel.

The regenerative furnace should be considered when the temperature and nature of the heating process, the size of the furnace, the cycle of operation or the plant conditions will not permit of a simpler or cheaper method of securing the result desired.

Regeneration, like recuperation, is really an indirect method of utilizing or recovering heat, and at times is limited to preheating the air alone, since certain fuels, such as natural gas and other hydrocarbon gases, cannot be preheated to the extent possible with producer gas. When the temperature requirements and plant conditions permit the use of furnaces with more direct methods of utilization or recovery, the regenerative principle is unnecessary. But where a high temperature is required, as for heavy forging, welding or melting operations, it is frequently necessary to resort to regeneration in order to establish a sufficient temperature differential, to increase the rate of heating, or to make possible the attainment of the desired working temperature, regardless of the saving in fuel or cost of furnace.

Considerable time is required to raise the temperature in the regenerative furnace from a comparatively cold condition to a relatively high working temperature. This is objectionable when the furnace is used only 8 or 10 hours per day, unless the heat is maintained between shifts to balance radiation and flue losses. Temperature requirements and the nature of the heating process or of the fuel may, however, make this furnace and practice desirable even under such intermittent operation. The objection does not hold when the furnace is operated continually at working temperature and capacity in two or more shifts.

Practically all regenerative furnaces are of the "batch" type, and therefore are limited in ability to maintain the chamber continually at full working capacity and at uniform temperature.

Regeneration should not be considered when the furnaces required are comparatively small and scattered. The floor space required for a regenerative furnace is

*Extracts from a bulletin (copyrighted) by W. S. Rockwell Co., entitled "The Variety of Furnaces."

relatively large, due to the area of the regenerators, reversing valves, flues and chimney, which frequently occupy a greater space than the furnace itself. This, with the heavier foundations required, must be considered with the production requirements, plant conditions and the space available for the furnaces, machines and operatives.

There is a limit in the size of a regenerative furnace below which it is impracticable to go, because the possible economy in fuel is outweighed by other considerations related to the cost of installation and operation.

The tendency to consider the regenerative or recuperative furnace as a possible solution of the so-called fuel problem should lead to consideration of conditions responsible for the limited use of such furnaces in the past and the extent of their use in the future.

The flexibility of such highly concentrated fuels as natural gas and oil and their relative cheapness in the past made it possible for the manufacturer to conduct many of his heating operations without regard to fuel conservation. As fuel was cheap and apparently not worth saving, the regenerative furnace did not often appeal to him. Production, rather than cost of fuel, was the order of the day. This, with a relatively low labor cost and working conditions not now countenanced, have been responsible for the lack of progress in furnace design that should have followed as a matter of course.

Changing conditions and the demand for better quality and decreased cost, coupled with relatively higher prices for material, fuel and labor, will compel an increasing appreciation of all the factors that control the selection and use of furnaces and fuels for the production of heat-treated products.

Magma Pump

A special pump designed to handle viscous fluids such as tar, heavy crude oils, pulp, molasses, etc., has been developed recently by the A. S. Cameron Steam Pump Works.

These Cameron Magma pumps are of the direct-acting piston plunger type operated either with steam or compressed air. The pump end is of special construction, with ports of such generous proportions that

CAMERON MAGMA PUMP

the liquid and foreign matter, held in suspension, are afforded unimpeded passages; also the discharge valves, instead of being of the flat type, are bowl-shaped and easily reseal themselves by the inclosed valve spring when the piston starts in the reverse direction. These discharge valves are particularly simple in construction, operate in a vertical plane and are very accessible.

The pump cylinder has either a removable cast-iron

or bronze bushing through which a solid grooved piston works. The grooved piston has the effect of helping to keep the bushing lubricated, and also, as this pump is designed to handle viscous fluids, these grooves eliminate the necessity of packing of any kind.

Referring to the sectional view of the pump: *G* is the cylinder, *F* is the piston and *A* the port connected with the source of supply. The necessity for inlet valves is eliminated by having the pump placed below the level of the source of supply. In this way the fluid comes readily into the pump through port *A*. From port *A* it passes into chamber *B*. The piston *F* in its travel closes the port *B*, leaving the fluid free to pass into the opposite end of the cylinder *G*, in which a partial vacuum has been created. The return of the piston forces the fluid into chamber *C* and up through bowl valve *D*. The discharge opening is designated by the letter *E*.

The driving end is of the standard steam-thrown valve type used in other Cameron pumps.

Synopsis of Recent Chemical & Metallurgical Literature

Metallography of the Oxyacetylene Weld as Affected by Enameling.—In the July, 1921, issue of the *Journal of the American Ceramic Society* is an interesting article by Emerson P. Poste, on "The Metallography of the Oxyacetylene Weld as Affected by Enameling." A discussion of the cooling of steel through the critical range is followed by consideration of the general structure of low-carbon material and of mechanical and thermal treatment, including the statement of the essential conditions for annealing. The temperature reached by the steel in the enameling operation is discussed with reference to the annealing temperature. An examination of plates and welds before and after enameling shows that a thorough annealing of the weld is accomplished during the process.

Action of Titanium in Blast-Furnace Slags.—Much attention has been given to the possibilities of commercial utilization of titaniferous iron ores, in view of their abundance, accessibility, high iron content and unusually low sulphur and phosphorus. If the titanium could be handled, the pig iron resulting should be excellent for bessemer steel. Indeed such ores were used for centuries in certain European forges. Despite a 6-year campaign at Sanford Hill, Dr. Forbes' successful experiment in 1868 at Norton, England, Dr. Rossi's more recent work at Niagara Falls, N. Y., in 1914 and at Patea, New Zealand, titaniferous ores are not wanted by the modern blast-furnace plant.

In the course of studies at Queen's University, Kingston, Ont., it occurred to the investigators that a great commercial drawback is due to the fact that titanium is always reckoned as an acid substance in computing the burden, and a corresponding amount of limestone is added to neutralize it. High titanium in a charge thus meant large amounts of stone and a corresponding low iron. But from its chemical characteristics titanium should act either as an acid or a base, depending upon whether the slag were excessively basic or acid, respectively, much as alumina

TABLE I. TYPICAL SLAGS

	According to Stoughton	According to Feild and Royster	From McIntyre Furnace
FeO.....	33	35	3.46
SiO ₂	41	40	26.72
CaO.....	11	5.5	25.81
MgO.....	12	13	5.99
Al ₂ O ₃	..	..	11.86
TiO ₂	..	..	25.1

is now supposed to act in furnaces smelting copper or lead ores. W. M. Goodwin in vol. 13, *Transactions* of the Royal Society of Canada, June, 1921, reports some successful experiments designed to prove this supposition.

Comparison of a slag analysis from the McIntyre furnace in the Adirondacks with average analyses quoted in the literature (Table I) substantiated this contention.

An ore containing 67 per cent Fe_2O_3 and 11.8 per cent TiO_2 was therefore mixed with charcoal and sufficient silica sand to give a slag containing approximately 36 per cent SiO_2 , and smelted in a small arc furnace. Table II gives

TABLE II. RESULTS OF EXPERIMENTAL RUNS

	1	2	3	4
Slag Analysis: FeO	2.9	4.0	3.7	3.1
SiO ₂	44.5	35.3	35.6	36.2
CoO	7.0	6.0	8.1	8.4
MgO	13.2	12.1	10.8	10.6
Al ₂ O ₃	13.8	17.5	15.9	16.9
TiO ₂	17.4	26.1	25.6	21.7
MnO	0.3	0.3	0.6	0.4
Nature	Fluid	Fluid	Very fluid	Fluid
Pig Analysis: C	2.53	2.53	2.56	3.04
Si	4.99	3.91	1.28	1.90
Ti	0.02	0.02	0.01	0.01
Temperature, deg. C:				
Slag stream	1300	1200	1430	1390
Furnace lining	1360	1315	1325	1360

data on the results. Temperatures were taken by optical pyrometers, and for various reasons are thought to be considerably too low. Run 4 was chilled by too-rapid chargings, and the iron could not be tapped. However, all slags were quite fluid, despite the rather wide variation in composition, particularly the silica content. The iron should be suitable for some foundry purposes, or for steel making.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Oxyaldehydes.—Oxyaldehydes are prepared by the interaction of phenols or their derivatives with formaldehyde and a nitroso compound in the absence of an organic solvent. The preparation of vanillin by treating guaiacol and formaldehyde with p-nitrosodimethylaniline in aqueous hydrochloric acid solution is described. (Br. Pat. 164,715; not yet accepted. Société Chimique des Usines du Rhône, Paris. Aug. 4, 1921.)

Electrolytic Iron.—An electrolyte contains iron chloride and an aluminum salt or colloidal alumina. Aluminum chloride or sulphate may, for example, be added, or aluminum dissolved in the iron chloride solution. Hydrochloric acid may be added to redissolve precipitated alumina or to prevent its precipitation; or fresh aluminum salt may be added to compensate for precipitation. A suitable solution contains 200 to 250 g. of iron and 5 to 15 g. of aluminum per liter. Current densities of 5 to 10 amp. per sq.dm. may be used, and the temperature may be 75 to 80 deg. C. Cast iron anodes may be used. (Br. Pat. 164,725; not yet accepted. Société d'Electrochimie et d'Electrometallurgie, Paris. Aug. 4, 1921.)

Sodium Cyanide.—Sodium cyanide is obtained from mixtures or solutions containing it together with sodium chloride and alkaline earth compounds such as the product obtained by fusing calcium cyanamide with sodium chloride, by precipitating the alkaline earth by adding a suitable sodium salt, such as sodium sulphate or carbonate, and concentrating the solution at the same time, or subsequently so as to salt out the sodium chloride and leave the cyanide in solution. For this purpose sodium cyanide, or its mixture with sodium chloride, may be added to the solution. If an

excess of cyanide is used the part remaining undissolved may be recovered by leaching the remaining solids. (Br. Pat. 164,719; not yet accepted. Deutsche Gold und Silber-Scheide Anstalt, vorm. Rössler, Frankfurt-on-Main, Aug. 4, 1921.)

Electrolytic Chromium.—Chromium is deposited electrolytically from solutions of alkali chromites or mixtures of alkali chromites with other chromium compounds prepared by adding solutions of caustic alkalis to solutions of chromium salts. The alkali should be added in such quantity that the chromite formed is dissolved. In baths containing chrome alum or chromium sulphate, the green form should be used. (Br. Pat. 164,731; not yet accepted. E. Liebreich, Berlin. Aug. 4, 1921.)

Drying and Liquefying Nitrous Gases.—Water is removed from the gases produced by the oxidation of ammonia, to enable them to be condensed without injury to the refrigerating apparatus, by spraying with liquid nitrogen oxides in packed towers of known type. Preferably, the gases are first washed with nitric acid of less than 68 per cent strength to secure partial dehydration. Using gases containing from 1 to 19 per cent of nitrogen oxides and liquid nitrogen oxides, both at 15 deg. C., and with a preliminary washing with nitric acid of 15 to 50 per cent strength, the issuing gases are cooled to -2 to -20 deg. C., owing to the loss of latent heat of the evaporated nitrogen oxides. The gases, being practically free from water and nitrous and nitric acid vapors at this temperature, are then liquefied by cooling—for instance to -100 deg. C.—in a refrigerating apparatus such as is used for condensing nitrogen oxides obtained by the oxidation of nitrogen. A portion of the liquid nitrogen oxides so obtained is used for treating further quantities of nitrous gases. (Br. Pat. 164,734; not yet accepted. Officine Electrochimiche Dr. Rossi and C. Toniolo, Legnano, Italy. Aug. 4, 1921.)

Tropine Derivatives.—Tropinone monocarboxylic ester is obtained by partial saponification and elimination of carbon dioxide from tropinone dicarboxylic ester (which can be obtained by condensing together acetone dicarboxylic ester, succindialdehyde and methyl amine). In an example the dicarboxylic ester is boiled with alcoholic potash, acidified, supersaturated with ammonia, and the monocarboxylic ester isolated by extraction with ether or chlorinated hydrocarbons. (Br. Pat. 164,757; not yet accepted. Firm of E. Merck, O. Wolfes and H. Maeder, Darmstadt. Aug. 4, 1921.)

Artificial Silk.—Artificial silk filaments, threads and fibers of cellulose acetate and other esters of cellulose are treated with hot water or steam, solution of ammonium, calcium or potassium sulphocyanide, or acetic acid, and dried without tension, to render them more or less crinkled in appearance and softer to the touch and to reduce their luster, thereby obtaining a product resembling wool or hair. Water at a temperature of 80 deg. C. or at the boiling point may be used; solutions of the chemical substances are preferably used at ordinary temperatures. The threads may be wound into hanks before treatment, and the hanks may be cut into lengths and spun or twisted into chappe or spun silk form and afterward treated. (Br. Pat. 165,164. British Cellulose & Chemical Mfg. Co. Aug. 17, 1921.)

Tanning Fish Skins.—A process for tanning fish skins, such as the skins of catfish, skate, etc., consists in salting the skins; liming in a dilute solution, preferably softened with soda, the strength being progressively increased by additions of milk of lime; rinsing and, with or without puering, submitting to the action of a vegetable or chemical tanning agent which is only slightly acid or is neutralized. For chrome tanning, the skins are puered with weak chicken manure, then treated in a solution of sodium chloride to which hydrochloric acid is added gradually in increasing quantities. After soaking in soft water, the skins are then tanned in pure chromate in gradually increasing quantities, with or without the addition of hydrochloric acid. They are then washed in soft water and protected from the action of light, being subsequently treated with sodium thiosulphate or with soda and finally freed from acid by means of tepid water and chalk. (Br. Pat. 165,199. E. Knudsen, Orkadalen, Trondhjem, Norway. Aug. 17, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Many Plants Resuming Operations

Glassware.—The Ball Bros. Glass Mfg. Co., Muncie, Ind., manufacturer of fruit jars, is arranging for the immediate resumption of operations at its plant, giving employment to about 1,000 workers. For some time past only about 200 operatives have been engaged at the plant.

The Lippincott Glass Co., Alexandria, Ind., has resumed the operation of its 20-pot furnace, giving employment to about 300 persons on a division of time. It is planned to place all departments in service at an early date, with working force totaling about 500 men.

The Kane Window Glass Co., Kane, Pa., has resumed production at its plant, with employment of about 250 men. The American Window Glass Co., in the same city, has arranged for the immediate operation of a portion of its plant, employing about the same number of operatives.

Ceramic.—The Metropolitan Paving Brick Co., Canton, Pa., has placed its entire seven plants in operation for the first time in several years.

The W. S. George Pottery Co., Canonsburg, Pa., is operating on a normal basis, with employment of the usual working force. The Canonsburg Pottery Co., with plant on Meadow Lane, is also engaging under normal production.

The Standard Sanitary Manufacturing Co., Louisville, Ky., has adopted a night working schedule at its plant, giving employment to about 100 men. It is expected to increase this number to about 400 operatives gradually.

Rubber.—The New Jersey Rubber Co., Lambertville, N. J., has adopted a night schedule of operation at its mill on certain days.

Paper.—The Jessup & Moore Paper Co., Wilmington, Del., has resumed production under a 24-hour working schedule at its local paper mills, and at its pulp mills at New Castle, Del. Increased operations are also under way at the company's plants at Providence and Elkton, Md.

Metal.—The National Enameling & Stamping Co., Granite City, Ill., has resumed operations at its plant, following a shut-down for several months. Three furnaces will be used at the present time.

Sugar.—The American Sugar Refining Co., 117 Wall St., New York, N. Y., has resumed operations at its Chalmette refinery, following a shut-down of several weeks. All of the other refineries of the company are now in operation.

The Chemical Welfare of America

A very strong plea for the continuation of the license system, covering the admission of dyes and fine organic chemicals into the United States, was made Thursday noon, Oct. 13, by Dr. Ellwood Hendrick in an address before the Rochester Chamber of Commerce on the subject "The Chemical Welfare of America."

The license system was adopted at the request of President Wilson and was continued at the request of President Harding. It is virtually an embargo against German dyes and fine chemicals, but it permits importation of any chemical or dye which is not produced in the United States in quality, quantity or at a price making it desirable for use. Dr. Hendrick pointed out that if this embargo is not renewed when it expires Germany is in a position to flood the United States with dyes manufactured with cheap labor and from cheap raw materials so that within two weeks the dye industry of this country would be wrecked.

The history of the dye industry from its beginning in England in 1856 was outlined. Dr. Hendrick showed clearly how that "key" industry fell into the hands of capitalists who, of course, immediately eliminated all scientific research work and operated simply on a money-making basis.

The Germans, being rich after the Franco-Prussian war,

took up the dye industry and developed the scientific side. So within the period of the following forty years they not only developed the science of dye chemistry to a very high point but evolved the many chemical byproducts which are now common drugs, medicines and other useful organic chemicals. But the Germans also developed a new line of research which was unknown to the world until the fateful fall of Liège—the making of poison gases. These are direct products from the experimentation carried on in the dye factories of Germany.

Between 90 and 95 per cent of all the dyes needed can now be manufactured without difficulty in the United States, and these dyes can be made at a cost which will not unnecessarily add to the cost of the dyed materials. Two cents worth of dye will color a dozen pairs of stockings and the cost of dye for an excellent suit of clothes never exceeds the half-dollar mark. So the cost of dyes becomes a very insignificant factor. Labor costs, being high, tend to make the American dyer skimp in the use of his dyes and complaints result.

The plea for the preservation of the dye and organic chemical industry in the United States is not based alone on the value of this industry in its production of dyes and chemicals but on the fact that the plants stand always at the command of the Government, not to recruit or train soldiers or to incite warlike feeling, but as laboratories where scientific research may be continually carried on and which will immediately become arsenals of chemical warfare munitions.

Naturally everyone sincerely hopes that war will never come again, but should such a frightful thing occur the country that is making the greatest progress in science will be best equipped to turn out munitions of the nature that will insure its success.

Agreements for the limitation of armaments or elimination of chemical warfare are very good as far as they go. However, wars usually follow the breaking of contracts between nations and "when once the fight is on the lid is off."

"The opponents of the license system include the owners of certain woolen mills, the Amoskeag Company of New Hampshire and a number of sincere persons who are uninformed on the subject and who, like most of us, hate the word embargo," said Dr. Hendrick. "I would not number among those uninformed persons Senator Moses of New Hampshire, who, whatever his motives may be, conducts himself like an attorney for the Amoskeag Company, and leads the opposition for the licensing system."

"In favor of the continuance of the license system you will find the American Chemical Society, the American Drug Manufacturers Association and countless other organizations as well as large numbers of individuals who are fully informed on the real situation."

Over one hundred members of the Rochester Section of the American Chemical Society were in attendance with the business men to hear Dr. Hendrick.

Conference on Soap Specifications Planned

The soap section of the American Specialty Manufacturers' Association, which represents 90 per cent of the soap manufacturers of the country, has appointed a committee consisting of A. Campbell, of the Globe Soap Co., St. Bernard, Ohio, chairman; W. H. Raymond, of Armour & Co., Chicago; H. M. Thayer, of N. K. Fairbank & Co., Chicago, to confer with soap chemists of the Bureau of Standards of the Department of Commerce relative to the revision of soap specifications which are contained in Bureau of Standards Circular 62, issued in 1916. It is expected that a conference with the committee will be arranged shortly.

Industrial Cost Association to Meet

From Nov. 2 to 4 the Industrial Cost Association will hold its second National Cost Conference at the William Penn Hotel, Pittsburgh. Sessions will be open to members and executives and department heads of industrial plants. The advance program follows:

WEDNESDAY, NOV. 2

10:30 a. m. Opening of conference. Address by Horace S. Peck, comptroller, S-K-F Industries, Inc., New York, and national president, Industrial Cost Association.

1:45 p. m. Address of welcome. E. V. Babcock, Mayor of Pittsburgh and president, Babcock Lumber Co.

2:15 p. m. "What the Sales Manager Should Have From the Accounting Department," S. B. Taylor, general sales manager, S-K-F Industries, Inc., New York City.

4:15 p. m. "Inventories: Methods of Completing the Physical Count," E. C. Grimley, Victor Talking Machine Co., Camden, N. J. Discussion led by Christopher Haigh, supervisor of costs, General Electric Co., West Lynn, Mass.

8 p. m. "Responsibility of the Comptroller or Accountant in Times of Business Depression," F. S. Willett, comptroller, Dodge Manufacturing Co., Mishawaka, Ind. Discussion led by F. C. Poag, analyst, Allied Chemical & Dye Corporation, New York.

9:30 p. m. "Idleness and Its Relation to Industry, in Retrospect," T. W. Dinlocker, assistant comptroller, S-K-F Industries, Inc., New York, and A. W. Wainwright, works auditor, Skayef Ball Bearing Co., Hartford, Conn.

THURSDAY, NOV. 3

9 a. m. "Terminology," Addison Boren, Yale & Towne Manufacturing Co., Stamford, Conn., chairman, National Terminology Committee, Industrial Cost Association.

10 a. m. "Budgeting the Plant and Office," H. S. Breitenstein, chief accountant, Bureau of Accounting Revision, Department of Controller, City of Pittsburgh. Discussion led by Weston J. Hibbs, treasurer, U. G. I. Contracting Co., Philadelphia.

2 p. m. "Sanitation and Safety," J. B. Ayres, sanitation and safety engineer, National Tube Co., National Works, McKeesport, Pa. "Cost and Profits of Welfare, Sanitation and Safety," Major William Hogg, assistant to vice-president, National Tube Co., Pittsburgh, Pa.

7 p. m. Informal banquet, President Peck, toastmaster. "Looking Into the Future," Newcomb Carlton, president, Western Union Telegraph Co., New York. "Federal Taxation," Sanford Robinson, New York City.

FRIDAY, NOV. 4

9 a. m. "How Can a Cost System, Although Efficient, Demoralize an Organization?" J. M. Howell, supervisor of costs, General Electric Co., Schenectady, N. Y. Discussion led by Ernest J. Wessen, cost engineer, W. T. Rawleigh Co., Freeport, Ill.

10:30 a. m. Reports of committees on "Distribution of Burden in Abnormal Times," "Trade Association Uniform Cost Systems," etc.

2 p. m. Plant visits.

All those planning to attend the conference are requested to notify immediately the national secretary, A. A. Alles, Jr., 2828 Smallman St., Pittsburgh, Pa.

Industrial Electric Heating Directory Planned

The Industrial Heating Division of the Power Sales Bureau of the National Electric Light Association is about to compile a directory of manufacturers and users of industrial electric heating equipment.

This includes the following equipment which is electrically heated: Steel furnaces, non-ferrous furnaces, heat-treating furnaces, japanning ovens, drying ovens, core ovens, bread-baking ovens (commercial), welding, rivet heating, electrochemical equipment.

Manufacturers and users of such equipment are requested to furnish data to R. T. Kaighin, care of Cleveland Electric Illuminating Co., Cleveland, Ohio.

Program, American Gas Association Meeting

The third annual convention and exhibition of the American Gas Association will be held in Chicago, Nov. 7 to 12, with headquarters at the Congress and Auditorium hotels. The following program has been arranged for the Technical Section:

WEDNESDAY AFTERNOON, NOV. 9, 2 O'CLOCK

Opening remarks and report of chairman, R. B. Harper, Peoples Gas Light & Coke Co., Chicago, Ill.

Report of nominating committee and election of officers, L. R. Dutton, chairman, Philadelphia Suburban Gas & Electric Co., Jenkintown, Pa.

Paper: "What Goes On in a Water Gas Machine?" M. E. Benesh, Peoples Gas Light & Coke Co., Chicago, Ill.

Report of committee on complete gasification of coal, A. W. Warner, chairman, Philadelphia Suburban Gas & Electric Co., Chester, Pa.

Report of gas oil committee, W. H. Fulweiler, chairman, United Gas Improvement Co., Philadelphia, Pa.

Report of refractory materials committee, W. H. Fulweiler, chairman, United Gas Improvement Co., Philadelphia, Pa.

THURSDAY AFTERNOON, NOV. 10, 2 O'CLOCK

Report of committee on increasing distribution capacity, C. N. Chubb, chairman, United Light & Railways Co., Davenport, Ia.

Paper: "Utilization of Compressed Air for Clearing Gas Piping," J. T. Griffin, Consolidated Gas, Electric Light & Power Co., Baltimore, Md.

Report of committee on consumers' meters, J. A. Clark, Jr., chairman, Public Service Gas Co., Newark, N. J.

Report of cast-iron pipe standards committee, Walton Forstall, chairman, United Gas Improvement Co., Philadelphia, Pa.

THURSDAY AFTERNOON, NOV. 10, 2 O'CLOCK

Report of chemical committee, C. A. Lunn, chairman, Consolidated Gas Co., New York, N. Y.

Report of purification committee, A. C. Fieldner, chairman, Bureau of Mines, Pittsburgh, Pa.

Effect of moisture on activity and capacity of iron oxides for gas purification, William A. Dunkley, Bureau of Mines, Urbana, Ill.

Seaboard liquid process for gas purification, F. W. Sperr, Jr., Koppers Co., Pittsburgh, Pa.

Determination of hydrogen sulphide in illuminating gas, C. W. Jordan, United Gas Improvement Co., Philadelphia, Pa., and W. H. Fulweiler, United Gas Improvement Co., Philadelphia, Pa.

FRIDAY AFTERNOON, NOV. 11, 2 O'CLOCK

Paper: "Some Experiments With the Mixing of Different Gravity Gases in Holders," H. E. Bates, assistant to engineer, Peoples Gas Light & Coke Co., Chicago, Ill.

Report of committee on deposits in gas pipes and meters, O. A. Morhous, chairman, Consolidated Gas Co., Astoria, L. I., N. Y.

Report of carbonization committee, J. Hawley Taussig, chairman, U. G. I. Contracting Co., Philadelphia, Pa.

Report of committee on disposal of waste from gas plants, F. W. Sperr, Jr., chairman, Koppers Co., Pittsburgh, Pa.

In addition, a paper, "Why Should Gas Companies Sell Their Tar to Distillers Instead of Working It Themselves?" by R. P. Perry, vice-president The Barrett Co., will be presented at the general session, Thursday morning, Nov. 10, at 10 o'clock.

To Study Medicinal Properties of Gases

Studies of the physiological effects of war gases has led some of the chemists of the Chemical Warfare Service to believe that certain gases may be beneficial in the treatment of diseases of the nose, throat and lungs. Some research along that line is to be attempted at Edgewood and General Fries is acquainting medical schools and research institutions with these findings in the hope that they may take up experiments of that character.

Hammer-Welded Joints in Penstock Withstand Bursting Pressures

Engineering News-Record for Oct. 20, 1921, reports the bursting of a 6 ft. hammer-welded penstock on the Big Creek No. 8 hydro-electric plant of the Southern California Edison Co. The break occurred immediately after a short circuit on the electrical system had caused a corresponding disturbance in the hydraulic lines; in fact, the conditions were such that a severe water hammer may easily have caused excessive pressure in the pipe. The static head at the point in question was 560 ft., the pipe had passed a shop test 50 per cent in excess of this load, and the completed penstock had been tested under full static head without indicating any weakness.

A sketch of the pipe, furnished by the M. W. Kellogg Co., the maker, is shown in the accompanying illustration.

Early reports stated that near point A, a $\frac{1}{2} \times 2\frac{1}{2}$ -in. discoloration on the fracture indicated a defect in the weld between plate and manhole casting. Microscopic examination of the metal by the New York Testing Laboratories showed this defect to be an accumulation of slag inclusions in the cast metal. Doubtless this defect was responsible for initiating the tear. The break passed along the manhole-ring casting, but did not cut across the ring. Except at this manhole, the break did not follow welded joints, but went through original metal. The longitudinal tear crossed a circumferential weld, and the circumferential part of the break occurred about a foot beyond that weld. In all there were 5,000 lin.ft. of hammer-welded joint in the penstock, none of which gave any evidence of weakness under the unusual stresses set up by the accident.

Labor Troubles in the German Chemical Industry

A message from Frankfort-on-Main says that the Chemical Industry Employers' Union and representatives of the workers' unions have come to an agreement respecting the resumption of work in the factories which have been closed—the Chemische Fabrik Griesheim-Elektron at Griesheim, the Farbwerke Hoechst and the Vereinigte Kunstseidefabriken Kelsterbach.

The agreement is based on the chemical industry's imperial tariff and the chemical industry's district agreement. The reinstatement of the dismissed workers will take place as requirements demand and as the managements of the works shall decide. No indemnification for the days lost will be paid.

The staff of the Griesheim-Elektron works has rejected this agreement by 1,202 to 236 votes, but less than 50 per cent of the workers used their votes.

Dye and Chemical Control Extended

By an overwhelming vote on Oct. 18 the House of Representatives passed the bill extending until Feb. 1 the emergency tariff bill, one section of which authorizes the control of the imports of dyes and certain chemicals. The dye control feature of the bill did not receive general discussion, although Representative Frear of Wisconsin took advantage of the opportunity to denounce the Chemical

Foundation and the embargo plan of protecting the dye industry. Mr. Frear took exception to remarks attributed to Mr. Garvan intimating that the German dye trust is able to influence members of the United States Senate and House of Representatives. So far as his own attitude is concerned, Mr. Frear stated, he is influenced "by the fact that the American public was paying four prices for its dyes and poor dyes at that."

In the course of his remarks Mr. Frear intimated that the investigation of the so-called dye lobby authorized in July might be taken up in the near future.

Glass Standardization Conference

Standardization of the different kinds, qualities and sizes of window and plate glass used as a building material and for many other purposes was discussed at a conference of glass distributors, architects and engineers of the Bureau of Standards of the Department of Commerce held on Oct. 19, at the Bureau of Standards.

Confusion is declared to exist in the glass and glazing fields so far as qualities and sizes of glass are concerned, and this conference outlined a program that will be participated in by the manufacturers, distributors, architects and the Bureau of Standards, and which it is believed will result in the elimination of unnecessary sizes, standardize quality and enable a more efficient use of this building material.

The task, as outlined at the conference, included the formation of a commercially usable scientific classification of glass. At present building glass is classified as rolled plate glass, blown cylinder or drawn sheet glass. The plate glass includes polished glass ranging in grade from that used for the highest quality mirrors to that used for skylights, different kinds of glass in which wire netting has been placed to prevent shattering and ornamental glass of various sorts. The drawn sheet glass is used for windows in different qualities.

Committees were designated by the conference to gather data on and consider different phases of the window and plate glass situation.

At a later date after the committees have had time to accomplish something, another conference will be called.

Those present at the conference were: J. W. Ginder, office of the Supervising Architect; Sullivan W. Jones, American Institute of Architects; S. F. Voorhees, American Institute of Architects; George H. Mayer, American Window Glass Co., Pittsburgh, Pa.; W. C. McCance, local manager, Pittsburgh Plate Glass Co., Baltimore, Md.; S. C. Gilmore, secretary, Hires-Turner Glass Co.; R. W. Spille, local manager, Hires-Turner Glass Co.; L. P. Forman, American Window Glass Co., Pittsburgh, Pa.; R. J. Potbury, Bureau of Yards and Docks, Navy Department; F. C. Brown, N. F. Harriman, P. H. Bates, W. A. Hull and A. E. Williams of the Bureau of Standards.

New Chemical and Oil Companies

During the month of September 35 new companies, with capital of \$50,000 or over, were organized to manufacture chemicals, chemical byproducts, dyes and affiliated products. The total capitalization was \$7,450,000, as compared with an aggregate capital of \$7,720,000 for 37 companies organized in the same month of last year and \$15,495,000 aggregate capitalization of companies in this line organized in August, 1921. The indicated investment of companies in the chemical industry for the first nine months of the present year, January-September, totals \$91,835,000, as against \$175,642,000 for the corresponding period of a year ago.

Oil companies organized during the same month of September, 1921, totaled 66, with an authorized capital of \$50,000 or larger. The total indicated investment of the companies stands at \$53,862,000, as compared with \$136,100,000 in the same month of a year ago and \$141,544,000 in August of the present year. It is the third lowest month for organizations of this character in 1921, the peak month of which was April, with total indicated capitalization of companies of \$227,470,000. For the first nine months of the present year the indicated capital investment aggregates \$1,046,463,600, divided among 752 organizations. In the corresponding period of 1920, 2,212 companies were formed, with a combined authorized capital of \$1,913,976,700.

Personal

J. O. ELTON, recently assistant manager of the Great Falls smelter of the Anaconda Copper Mining Co., is assistant general manager for the International Smelting Co., succeeding O. M. Kuchs.

C. POWELL KARR, metallurgist with the Bureau of Standards and an authority on non-ferrous alloys, has been appointed a member of the engineering committee of the National Research Council, which has to do with investigations of molding sand and foundry refractories.

O. M. KUCHS, who has been assistant general manager in Utah for the International Smelting Co., has become general manager for the Andes Copper Mining Co., with headquarters at Potrerillos, Chile. He sails from New York on Oct. 26.

H. C. PARMELEE addressed the junior and senior classes in chemical engineering at the Sheffield Scientific School of Yale University, Oct. 19.

FLOYD W. PARSONS has been appointed editorial director of *Gas Age-Record*. Formerly Mr. Parsons was editor of *Coal Age*, one of the McGraw-Hill engineering publications, and later conducted a department in the *Saturday Evening Post* under the title "Everybody's Business."

W. N. WATSON and C. F. NORTH, chemists for the U. S. Tariff Commission, have been transferred to the Treasury Department for work in New York in connection with the special investigation of American valuation.

S. L. WILLIS, who was formerly in charge of ceramic investigations for the U. S. Tariff Commission, has resigned to accept a position with the Corning Glass Co.

W. W. WITMER has recently become associated with the Hoskins Process Development Co., Chicago. Since graduating at Purdue University in 1909 Mr. Witmer has been employed by the du Pont company. He has been located at Repauno, N. J., Barksdale, Wis., Louviers, Col., and du Pont, Wash., holding positions ranging from chemist to assistant manager of the Barksdale plant.

Obituary

Colonel SPENCER BORDEN, chemist and manufacturer, of Fall River, Mass., died suddenly of heart trouble at the Woodstock Inn, Woodstock, Vt., on Oct. 17. He had been associated with Thomas A. Edison in his early work and had organized the New England branch of the latter's business. Colonel Borden was seventy-two years old.

JOHN G. LUKE, president of the West Virginia Pulp & Paper Co. and a pioneer manufacturer of sulphite pulp, died on Oct. 15 in St. Luke's Hospital in New York City, following an operation two weeks previously for appendicitis. Mr. Luke was born on April 29, 1857, in Rockland, Del., where his father was employed as superintendent of the mills of the Jessup & Moore Paper Co. The son entered the employ of this mill at the age of sixteen, and subsequently worked in several of the largest paper mills in this country. As superintendent of the Richmond Paper Co. of Richmond, Va., he became familiar with the sulphite process, which was then in an experimental stage, and from the experience gained in this plant he organized his own company and built a mill at Piedmont, W. Va. This was the beginning of the West Virginia Pulp & Paper Co.

Prof. J. ERNEST WOODLAND, head of the science department of Mechanics Institute of Rochester, N. Y., died on Oct. 17 of apoplexy. Prof. Woodland, who was fifty-five years of age, was formerly a member of the faculty of the University of Rochester and at one time was chairman of the Rochester Section of the American Chemical Society.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Oct. 24, 1921.

The pending railroad strike stimulated buying of chemicals during the past week and the market has shown more action than at any time so far this year. The movement gained more strength as the week progressed and in some directions demand has been greater than the available supply of material. There were some, however, who viewed the situation quite pessimistically and believed that should the controversy be straightened out before the time set for the walkout, conditions would be far more serious than the recent depression. Consumers all around are showing an added interest, and indications clearly point to a steady development. The recovery in prices made by various basic chemicals is significant that the reaction has about been completed and those close to the pulse of trading are convinced that production is well adjusted and that normality in market conditions is only a matter of a short time. The most encouraging feature at present is the interest shown by the leading domestic consumers, and among these are the paper, paint and soap industries. Paper mills have been buying in larger volume during the past few weeks and bleaching powder manufacturers have found a steady market for their entire output. Soap-makers have purchased large quantities of imported caustic potash and were eager to stock up additional quantities at the close of the week. The textile industry has been a steady buyer of chemicals, but purchases were chiefly for small quantities.

CHEMICALS

Prices on *caustic potash*, 88-92 per cent, have once more regained their steadiness under an improved consuming inquiry for spot and future shipments. Some material was available at 5½c. per lb. for imported, but the general quotation among first-hand holders was 6c. Factors in this product believe that the market is slated for considerably higher prices before the turn of the year. Shipments were nominal, with 5½c. asked subject to cable confirmation. *Bichromate of soda* is slightly higher on spot, with sales recorded at 7½c. per lb. The demand for this product is increasing and sellers state that they have received a greater amount of inquiries during the past week. Producers quote the market at 8c. per lb. Spot supplies of *cyanide of soda*, imported, are very scarce and the market is decidedly stronger and higher. German 120 per cent is quoted at 25c. per lb., which is considered an inside price by the few holders of spot material. Goods afloat are held at 22c. per lb. For the 128 per cent German make afloat 25c. per lb. was named. French 125-128 per cent for shipment is offered at 23c. per lb. Prices on *nitrite of soda* are somewhat firmer and business is reported slightly better, even though actual orders call for small quantities only. Sellers quote the domestic brands at 6¾c. per lb. and the imported at 6½c. Prices on *prussiate of soda* have advanced sharply since the beginning of the week under an active inquiry and a scarcity of supplies. Holders are asking up to 15c. per lb. for imported material. Sales of spot goods are reported as high as 14½c. per lb. and this price is also named for October shipment from abroad. November-December shipments are held at 14½c. per lb. The demand for solid *caustic soda* has continued quite active so far this month. While there still are a few lots at 4c. per lb., the majority of holders are above this level for standard brand goods and quote \$4.05 per 100 lb. ex-store. Sales of outside brands have gone through at \$3.90 per 100 lb., but these are fast dwindling from the market. Manufacturers are still quoting unchanged figures at the works for contracts over the year. Spot *ammonium sulphate* in double bags for export is quite difficult to locate and odd lots picked up here and there have brought \$2.75 per 100 lb. Makers are quoting single bags at \$2.75 per 100 lb. ex-dock New

York for small quantities. The market is in an extremely firm position with supplies almost impossible to find and demand very acute both from domestic and export buyers. Prices on *barium chloride* from abroad have been much firmer and quotations from importers are higher at \$46@ \$49 per ton for prime material. Domestic makers are still unable to compete. Prices on *nitrate of soda* are much firmer. Importers have announced an advance in price for futures, but have not named any definite quotation. Spot and future deliveries are higher at \$2.35@ \$2.45 per 100 lb. Imported *permanganate of potash* U.S.P. is quoted lower at 18c. per lb. Single bags of light *soda ash* in less than carload lots are moving freely at \$2.10 per 100 lb. and upward. Large dealers state that 2c. per lb. could probably be done for carlots, although the tone of the market is quite firm. Sales of barrels are reported at \$2.45@ \$2.50 per 100 lb. Prices remain unchanged at the works. Trading in *glycerine* during the week was very light, with little variation in price. Dynamite sold at 12c. per lb. and c.p. at 14½c. per lb. in drums. Leading producers of *copper sulphate* are still quoting at the former basis of 5½c. per lb. for carload quantities of standard 99 per cent. large crystals. The tone of the market is somewhat firmer with the advance in copper. There were quantities of imported material on the spot market that sold down to 5c. per lb., but these are being taken off the market very quickly.

COAL-TAR PRODUCTS

Buying in the coal-tar products industry has been somewhat spotty, with a lack of interest noted early in the week and a decided improvement during the last few days. The latter part of the week was experienced by a constant increase in the number of orders and inquiries and the market all around reflected a renewed activity to a considerable extent. The definite extension of the provisions of the emergency tariff until Feb. 1, 1922, is expected to lead to some fairly good buying, as most consumers have been holding off purchasing until some definite action had been taken. The scarcity of benzene is affecting production of many other products and in some instances makers have had to shut down until supplies can be procured. Resale stocks of most commodities are being taken off the market gradually and makers seem well satisfied with this method of obtaining normality in the market. Prices are generally quoted at former levels, but real business is being transacted at slightly under listed prices. The demand for *benzene* is exceeding the supply and no immediate relief can be seen in view of the present output of coke ovens, which even with the recent increase is only at 25 per cent normal. Resale stocks are very hard to locate and are generally held at 40c. per gal. Refiners' prices for future delivery are 27@33c. per gal. A slight improvement in *naphthalene flakes* was reported, but the balls have remained dormant. Some sellers are inclined to be firmer in their views, but supplies are still plentiful and sales around 6½c. per lb. are still being made. First hands ask up to 8c. per lb., but not very much business is being placed at these levels. Official Government resellers of *phenol* ask 12c. per lb., but prime goods on the open market can be had down to 9½c. per lb. There were a few sales recorded at 9c. per lb. during the past few days and the inquiry seems to be increasing. Resale stocks of *aniline oil* are large and buying must become far more active before the market can be called steady, even though there is a scarcity of benzene. The general asking price is 18c. per lb., but sales were made at the close of the week down to 17c. per lb. Resellers of *dimethylaniline* are obtaining the passing business at 41c. per lb., which is about 5c. per lb. under the makers. The demand is fairly active and the market is a trifle firmer, as most of the second-hand material is being cleared off the market. Manufacturers of *dinitrobenzene* have sold as low as 21c. per lb. during the week on actual business. Quotations, however, are given at 23@25c. per lb., according to brand and quantity. Producers of *paranitraniline* are quoting former prices of 77@80c. per lb. according to brand. Business around the trade on this product has been more or less fair, but rumors of imported German goods at ridiculously low figures have put a dent in any real trading.

The Chicago Market

CHICAGO, Oct. 21, 1921.

There was little or no change in the general chemical market during the past two weeks. Most factors report a very good volume of business and all are apparently satisfied. The bulk of the business continues to be for small quantities but occasionally a large order is noted. Prices are firm as a rule although with actual business in sight many of the regular prices can be shaded. This is noticeable especially among the smaller factors. The railroad situation is firming up prices and any radical reductions can scarcely be expected for some time. The fact that quite a few speculators are taking on rather heavy stocks shows that at least some are expecting a rising market.

INDUSTRIAL CHEMICALS

The *caustic soda* situation lacks new developments and prices are unchanged. Supplies are not heavy and 4½c. for the ground 76 per cent and 4c. for the solid were the best prices noted. *Soda ash* continues to move well and is firm at \$2.60 per 100 lb. for material in cooperage. *Potash alum* appears to be enjoying a good demand and 5½c. per lb. for the lump and 6½c. for the powdered were the prevailing quotations. *Sal ammoniac* is rather quiet and supplies are available at 7½c@7¾c. per lb. for the white granular 98-100 per cent. There was a brisk demand for *carbon tetrachloride* and 10½c. for large drums was the inside figure. *Formaldehyde* is still very quiet, with 12c. per lb. the figure generally named, although this could probably be shaded slightly. *Glycerine* has shown but little activity and the price lacks quotable change. Refiners are asking 14½c.@14¾c. per lb. for the large drums.

Caustic potash continues firm and unchanged in price, with supplies available at 6½c. per lb. for the 88-92 per cent grade. *Potassium bichromate* is quoted at 13c.@13½c. per lb. and the soda at 9½c. for single casks. A decline of 1c. per lb. was noted in some quarters on *potassium permanganate*, and U.S.P. crystals of foreign origin are now available at 23c. for small lots. *Bicarbonate of soda* is offered at \$2.60 per 100 lb. for single barrels. *Sodium fluoride* is not so active, but prices are unchanged at 11c.@12c. per lb. according to quantity. *Zinc sulphate* is quiet at 3½c. per lb. for the tech. cryst. in single barrel lots.

No changes of any consequence were noted in the list of acids. Supplies are plentiful and are said to be moving well. *Acetic acid* is firm, with supplies of the 28 per cent available at \$2.65@ \$2.75 per 100 lb. and glacial at \$10.25 to \$10.75. *Oxalic acid* is in fair demand at 17c. per lb. *Citric* and *tartaric acids* are very quiet, with domestic makers apparently in control of the market. *Hydrochloric acid* is quiet and unchanged as to price.

The Iron and Steel Market

PITTSBURGH, Oct. 21, 1921.

There has been very little change in the iron and steel market situation in the past week. There was such steady increase in demand after the turn that occurred about the middle of July that a failure in the market to improve seems very like a backset, and this may account for the somewhat unfavorable view of the market situation entertained in some quarters this week.

There is no evidence, however, that demand for steel products has actually fallen off in any particular. The record of production up to this week is one of practically constant increases. Steel ingot production seems now to be at somewhat more than 35 per cent of capacity, this comparing with an average rate of about 32 per cent in September, while at the low point, about the middle of last July, the rate was under 20 per cent.

As everyone is more or less interested in the threat of a railroad strike, beginning October 30, there has naturally been an effort to discern an influence of the strike talk upon the state of the steel market. It does not appear, however, that the actual market has taken much cognizance of the possibility of a railroad strike, and that is natural enough after all, for what should a buyer or seller do if he expects a railroad strike? Should he buy or not buy, or should he sell or not sell?

Of more importance to the steel market, unquestionably,

is the matter of freight rates. Reductions have been expected for a long time, and buyers are probably taking more interest now, seeing that there is a somewhat nearer approach of the expected reductions. Producers of steel, in defending their prices during the last few months, have laid much stress upon the influence of high freight rates on their raw and intermediate materials, in making high costs as compared with conditions in 1913, and therefore high selling prices. Naturally buyers of steel would expect lower prices in the event of freight rate reductions. Whether this would affect their buying conduct is a question, if it is true as has been claimed that at best purchases of steel have been for immediate utilization only. Forward buying has been absent from the market, and buying for immediate use could not well be postponed. As to freights on steel bought, buyers would in general get the benefit of rate reductions irrespective of date of purchase, since sales are usually made on a delivered basis with a freight allowance.

OPERATIONS

As formerly, the sheet branch leads the divisions of the finished steel trade in point of mill activity, with an operation of about 90 per cent in the Steel Corporation's sheet mills and an operation probably over 75 per cent among the independent sheet mills. The trend, however, is slightly downward. Tin plate mill activity is distinctly on the decrease, with an operation of 50 to 55 per cent this week, but the bulge in activity that began in September was quite out of season. The various wire and pipe mills are operating generally at between 40 and 60 per cent. These are high percentages when the rate of ingot production is not much over 35 per cent, but operations at bar, shape, plate and rail mills are very light. Bar mills are doing the best of the four classes. Structural mill operations have been increasing lately. The Bridge Builders' and Structural Society reports fabricated steel lettings in September at 48 per cent of the fabricating shop capacity, against 33 per cent for August and an average of 28 per cent in the eight months ended with August. A few releases on rail contracts have been received in the past two or three weeks, but rail production is nevertheless very light. Contracts for this year were not heavy, but no small part of the tonnage will be carried over.

STEEL PRICES

On the whole it can be said that the trend in steel prices is toward stiffness. There is certainly no downward trend in general. There are, however, various cross-currents. In bars, shapes and plates several mills are firmer in their price views than a few weeks ago, but there is some aggressive selling with very close prices named, possibly a shade lower than two or three months ago. It is distinctly favorable, however, that the general level on these three products is not materially lower, even in a period of two or three months. In sheets the price situation is somewhat complicated. Nearly all the independent sheet mills have announced a second advance of \$5 a ton, following the one that occurred in September, but there is question whether the advance will really be established, and there is room for suspicion that there is a "paper" advance, made chiefly for the purpose of encouraging the placing of orders at the former prices. There is also the complication that while the advance now talked of would raise blue annealed from 2.50c. to 2.75c., there has been selling of late at the old price of 2.25c., ruling before the September advance. The September advances in black sheets to 3c. and in galvanized to 4c. are well held. In wire products 60-day contracts were made just before the Sept. 12 advance, and some small sales are now being made at the advanced prices, but it is understood that some attractive orders are being accepted at the old prices. Tubular goods are quite steady in price, with the usual exception of line pipe.

The pig-iron markets are distinctly dull, whether from consumption failing to increase or from buyers having renewed expectations of lower prices on account of prospective reductions in coke and limestone freight rates. Quotations in the local market are unchanged at \$20 for bessemer, \$19.25@20 for basic and \$21 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being \$1.96.

Sodium bichromate..... lb.	.07 - .08	.08 - .08
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphite powdered, U.S.P..... lb.	.04 - .05	.05 - .06
Sodium borate (borax)..... lb.	.05 - .06	.06 - .07
Sodium carbonate (sal soda)..... 100 lb.	1.75 - 1.90	2.00 - 2.25
Sodium chlorate..... lb.	.07 - .07	.08 - .08
Sodium cyanide..... lb.	.25 - .26	.27 - .30
Sodium fluoride..... lb.	.10 - .11	.11 - .12
Sodium hydroxide (caustic soda)..... 100 lb.	4.05 - 4.15	4.20 - 4.75
Sodium hyposulphite..... lb.		.03 - .03
Sodium nitrite..... lb.	.06 - .07	.07 - .07
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic..... lb.	.04 - .04	.04 - .05
Sodium potassium tartrate (Rochelle salts) lb.		.21 - .24
Sodium prussiate, yellow..... lb.	.14 - .14	.14 - .15
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 - 1.15	1.25 - 1.40
Sodium silicate, solution (60 deg.)..... lb.	.02 - .03	.03 - .03
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.04 - .04	.05 - .06
Sodium sulphite, crystals..... lb.	.03 - .03	.03 - .04
Strontium nitrate, powdered..... lb.	.12 - .13	.13 - .20
Sulphur chloride, red..... lb.	.05 - .05	.05 - .06
Sulphur, crude..... ton	18.00 - 20.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .08	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent..... lb.	.18 - .19	
Tin oxide..... lb.		.38 - .40
Zinc carbonate, precipitate..... lb.	.16 - .16	.17 - .17
Zinc chloride, gran..... lb.	.09 - .09	.10 - .11
Zinc cyanide..... lb.	.42 - .44	.45 - .47
Zinc dust..... lb.	.11 - .11	.11 - .12
Zinc oxide, XX..... lb.	.07 - .07	.08 - .09
Zinc sulphate..... 100 lb.	3.00 - 3.25	3.30 - 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.15 - \$1.20
Alpha-naphthol, refined..... lb.	1.25 - 1.30
Alpha-naphthylamine..... lb.	.17 - .20
Aniline oil, drums extra..... lb.	.17 - .20
Aniline salts..... lb.	.24 - .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.25 - 1.35
Benzidine, base..... lb.	.90 - 1.00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.52 - .55
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.50 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.31 - .34
Beta-naphthylamine, sublimed..... lb.	1.75 - 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .17
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.00 - 1.15
Dimethylaniline..... lb.	.41 - .50
Dinitrobenzene..... lb.	.23 - .27
Dinitrochlorobenzene..... lb.	.23 - .25
Dinitronaphthalene..... lb.	.30 - .35
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.25 - .30
Dip oil, 25%, car lots, in drums..... gal.	.30 - .35
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.10 - 1.20
Meta-phenylenediamine..... lb.	1.15 - 1.20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.60 - 1.70
Naphthalene crushed, in bbls..... lb.	.06 - .07
Naphthalene, flake..... lb.	.06 - .07
Naphthalene, balls..... lb.	.08 - .09
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.15 - .17
Ortho-amidophenol..... lb.	3.00 - 3.10
Ortho-dichlorobenzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-amidophenol, HCl..... lb.	1.70 - 1.80
Para-dichlorobenzene..... lb.	.12 - .15
Paranitroaniline..... lb.	.77 - .80
Para-nitrotoluene..... lb.	.80 - .85
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.40 - .50

Phenol, U. S. P., drums..... lb.	.09 - .12
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.50 - 1.60
Resorcinol, pure..... lb.	2.00 - 2.25
Salicylic acid, tech., in bbls..... lb.	.18 - .20
Salicylic acid, U. S. P..... lb.	.19 - .22
Salol..... lb.	.60 - .70
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.30 - 1.35
Toluidine, mixed..... lb.	.43 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .30

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.19 - \$0.20
Beeswax, refined, dark..... lb.	.24 - .25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.36 - .42
Candellila wax..... lb.	.24 - .25
Carnauba, No. 1..... lb.	.46 - .47
Carnauba, No. 2, North Country..... lb.	.24 - .24
Carnauba, No. 3, North Country..... lb.	.14 - .15
Japan..... lb.	.21 - .22
Montan, crude..... lb.	.05 - .05
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03 - .03
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 - .02
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .03
Paraffine waxes, refined, 125 m.p..... lb.	.03 - .03
Paraffine waxes, refined, 128-130 m.p..... lb.	.03 - .04
Paraffine waxes, refined, 133-135 m.p..... lb.	.04 - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 - .06
Stearic acid, single pressed..... lb.	.09 - .09
Stearic acid, double pressed..... lb.	.10 - .10
Stearic acid, triple pressed..... lb.	.11 - .11

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.55 - 5.65
Rosin E-I..... 280 lb.	5.75 - 6.25
Rosin K-N..... 280 lb.	6.35 - 6.75
Rosin W. G.-W. W..... 280 lb.	6.90 - 7.40
Wood rosin, bbl..... 280 lb.	6.25 - 6.25
Spirits of turpentine..... gal.	.74 - .74
Wood turpentine, steam dist..... gal.	.72 - .72
Wood turpentine, dest. dist..... gal.	.71 - .71
Pine tar pitch, bbl..... 200 lb.	 6.50
Tar, kiln burned, bbl. (500 lb.)..... bbl.	 11.00
Retort tar, bbl..... 500 lb.	 11.00
Rosin oil, first run..... gal.	.35 - .35
Rosin oil, second run..... gal.	.37 - .37
Rosin oil, third run..... gal.	.44 - .44
Pine oil, steam dist., sp.gr., 0.930-0.940..... gal.	1.90 - 1.90
Pine oil, pure, dest. dist..... gal.	1.50 - 1.50
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 - .46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 - .35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 - .75
Pine tar, ref., thin, sp.gr., 1.080-1.960..... gal.	.35 - .35
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25 - 1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 - .35
Pinewood creosote, ref..... gal.	.52 - .52

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 - .37
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 - .35
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 - .34
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 - .23

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.70 - 3.00
Blood, dried, f.o.b., N. Y..... unit	4.00 - 4.00
Bone, 3 and 50, ground, raw..... ton	30.00 - 32.00
Cyanamide, f.o.b. works..... unit	4.50 - 4.50
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 - 3.00
Nitrate soda..... 100 lb.	2.35 - 2.45
Tankage, high grade, f.o.b. Chicago..... unit	3.00 - 3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	4.50 - 6.50
Tennessee, 78-80 p.c..... ton	8.00 - 9.00
Potassium muriate, 80 p.c..... ton	37.50 - 40.00
Potassium sulphate..... unit	1.15 - 1.20

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 - .21
Upriver coarse..... lb.	.11 - .12
Upriver caucho ball..... lb.	.11 - .12
Plantation—First latex crepe..... lb.	.15 - .15
Ribbed smoked sheets..... lb.	.15 - .15
Brown crepe, thin, clean..... lb.	.15 - .15
Amber crepe No. 1..... lb.	.17 - .17

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 - \$0.10
Castor oil, AA, in bbls..... lb.	.11 - .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.15 - .16
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09 - .10
Cocoonut oil, Cochin grade, in bbls..... lb.	.10 - .11
Corn oil, crude, in bbls..... lb.	.09 - .09
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07 - .07
Cottonseed oil, summer yellow..... lb.	.08 - .09
Cottonseed oil, winter yellow..... lb.	.09 - .09

Linseed oil, raw, car lots (domestic)	gal.	.68	—	.69
Linseed oil, raw, tank cars (domestic)	gal.	.63	—	.64
Linseed oil, in 5-bbl lots (domestic)	gal.	.71	—	.72
Olive oil, Denatured	gal.	\$1.15	—	\$1.20
Palm, Lagos	lb.	.07	—	.07½
Palm, Niger	lb.	.06½	—	.06½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08	—	.08½
Peanut oil, refined, in bbls.	lb.	.11½	—	.11½
Rapeseed oil, refined in bbls.	gal.	.90	—	.91
Rapeseed oil, blown, in bbls.	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.08½	—	—
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.07½	—	—

FISH

Light pressed menhaden	gal.	\$0.40	—	—
Yellow bleached menhaden	gal.	.42	—	—
White bleached menhaden	gal.	.44	—	—
Blown menhaden	gal.	.48	—	—

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	20.00	—	24.00
Barytes, crude, 88% @ 94% ba., Kings Creek	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri	net ton	7.00	—	—
Blanc fixe, dry	lb.	.04	—	.04½
Blanc fixe, pulp	net ton	45.00	—	55.00
Casein	lb.	.07	—	.10
Chalk, Precipitated, domestic, extra light	lb.	.04½	—	.05
Chalk, Precipitated, domestic, light	lb.	.04	—	.04½
Chalk, Precipitated, domestic, heavy	lb.	.03½	—	.04
Chalk, Precipitated, English, extra light	lb.	.04½	—	.05
Chalk, Precipitated, English, light	lb.	.04½	—	.05
Chalk, Precipitated, English, dense	lb.	.04	—	.04½
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points	net ton	13.00	—	20.00
China clay (kaolin), imported, lump	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.	net ton	18.00	—	—
Fullers earth, imported, powdered	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality	lb.	.06	—	.07
Graphite, Ceylon chip	lb.	.04½	—	.05
Graphite, high grade amorphous crude	lb.	.00¾	—	.02½
Kieselguhr, f.o.b. mines, Cal.	per ton	40.00	—	—
Kieselguhr, f.o.b. N.Y.	per ton	61.00	—	—
Magnesite, calcined	per ton	66.00	—	70.00
Pumice stone, imported	lb.	.03	—	.40
Pumice stone, domestic, lump	lb.	.05	—	.05½
Pumice stone, domestic, ground	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore	net ton	—	—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore	net ton	—	—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore	net ton	—	—	17.00
Quartz, lump, f.o.b. North Carolina	net ton	5.00	—	7.50
Shellac, orange fine	lb.	.66	—	.68
Shellac, orange superfine	lb.	.70	—	.72
Shellac, A. C. garnet	lb.	.53	—	.55
Shellac, T. N.	lb.	.59	—	.61
Soapstone	ton	2.00	—	15.00
Sodium chloride	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars	ton	7.50	—	11.00
Talc, imported	ton	30.00	—	40.00
Talc, California talcum powder grade	ton	18.00	—	25.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh	per ton	\$50.00	—	—
Carborundum refractory brick, 9-in. { less than carlot	1,000	1250.00	—	—
Carborundum refractory brick, 9-in. { carload lots	1,000	1100.00	—	—
Chrome brick, f.o.b. Eastern shipping points	net ton	52-55	—	—
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30-32	—	—
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points	net ton	33-35	—	—
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	35-40	—	—
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	30-35	—	—
Magnesite brick, 9-in. straight	net ton	65-70	—	—
Magnesite brick, 9-in. arches, wedges and keys	net ton	77	—	—
Magnesite brick, soaps and splits	net ton	98	—	—
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	40-42	—	—
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	42-45	—	—
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.	1,000	35-38	—	—

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	\$200.00	—	\$225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, carlots	lb.	.11	—	—
Ferrochrome per lb. of Cr. contained, 4-6% carbon, carlots	lb.	.11	—	.12
Ferromanganese, 76-80% Mn, domestic	gross ton	60.00	—	63.00
Ferromanganese, 76-80% Mn, English & German	gross ton	59.00	—	60.00
Spiegelisen, 18-22% Mn	gross ton	25.00	—	27.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.25	—	—
Ferrosilicon, 10-15%	gross ton	38.00	—	40.00
Ferrosilicon, 50%	gross ton	60.00	—	65.00
Ferrosilicon, 75%	gross ton	130.00	—	135.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.40	—	.45
Ferrouanium, 35-50% of U, per lb. of U content	lb.	.60	—	—
Ferrovanadium, 30-40% per lb. of contained V	lb.	4.25	—	4.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content	net ton	\$8.00	—	\$10.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	ton	24.00	—	26.00
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard	ton	24.00	—	26.00
Coke, foundry, f.o.b. ovens	net ton	4.25	—	4.50
Coke, furnace, f.o.b. ovens	net ton	3.25	—	3.50
Coke, petroleum, refinery, Atlantic seaboard	net ton	12.00	—	13.00
Fluorspar, gravel, f.o.b. mines, New Mexico	net ton	15.00	—	—
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	net ton	20.00	—	22.00
Ilmenite, 52% TiO ₂ , per lb. ore	lb.	.01½	—	.01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.20	—	.21
Manganese ore, chemical (MnO ₂)	net ton	50.00	—	55.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.	lb.	.55	—	.60
Monazite, per unit of TbO ₂ , c.i.f., Atlantic seaport	unit	30.00	—	—
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	.12	—	.12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	.13	—	.13
Pyrites, domestic, fines, f.o.b. mines, Ga.	unit	.11	—	.12
Rutile, 95% TiO ₂ per lb. ore	lb.	.15	—	—
Tungsten, scheelite, 60% WO ₃ and over, per unit of WO ₃ (nominal)	unit	2.75	—	3.00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.	unit	3.00	—	3.25
Uranium ore (carnotite) per lb. of U ₃ O ₈	lb.	1.25	—	1.75
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	2.25	—	2.50
Vanadium pentoxide, 99%	lb.	2.00	—	14.00
Vanadium ore, per lb. of V ₂ O ₅ contained	lb.	1.00	—	—
Zircon, washed, iron free, f.o.b. Pablo, Florida	lb.	.04½	—	.13

Soft steel bands	3.42	3.48	3.48
Plates, ½ to 1 in. thick	2.83	2.88	2.88

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation California

SELMA—The Fresno Tire & Rubber Co., Fresno, Cal., is planning for the erection of a new plant at Selma, estimated to cost about \$200,000, including machinery.

MARIA—The Imperial Valley Gypsum & Oil Co., Spreckels Bldg., San Diego, Cal., has acquired property at Maria, Imperial Co., comprising about 170 acres of land, as a site for the erection of a new oil refinery and gypsum manufacturing plant. For raw material supply for the latter works, the company has purchased extensive deposits about 25 miles north of Maria. The initial plants are estimated to cost about \$150,000.

MARTINEZ—Fire, Oct. 5, damaged a portion of the local oil refinery of the Associated Oil Co., with loss estimated at about \$50,000.

BERKELEY—The Superior Tile & Products Co., 1910 Prince St., has preliminary plans under way for the erection of a new plant, estimated to cost about \$15,000.

CARPINTERIA—The Carpinteria Clay Products Co., recently organized with a capital of \$150,000, has commenced the operation of a local plant for the manufacture of brick and tile products. At a later date it is planned to expand the works, with department for the production of chinaware and other ceramic products. The company is headed by Lyman T. Gage, B. C. Sutton and L. L. Brentner.

Connecticut

NEW LONDON—The Massachusetts Oil Co., Pequot Ave., will make extensions in its local works, including the erection of a 1-story building, 30 x 75 ft., to cost about \$12,000.

Delaware

WILMINGTON—The Christiana Leather Co., headed by James J. O'Neill, president of the Wilmington Leather Co., is arranging for the early opening of its tannery, with initial capacity of about 250 skins per day. The plant will give employment to about 100 men.

Florida

PENSACOLA—The Southern Pine Extracts Co. is planning for the establishment of a new local plant for the manufacture of pine oils, turpentine and kindred products. James W. Ely is head.

JACKSONVILLE—The Tidewater Glass Mfg. Co. is perfecting plans for the erection of its proposed new local plant on waterfront property totaling 325 x 1,500 ft., recently acquired. The works will consist of three complete operating units, each 2-story, 60 x 300 ft., and estimated to cost about \$150,000, including machinery. The plant will specialize in the manufacture of glass bottles, jars, etc. Erection bids will soon be asked. B. R. Kessler is secretary.

Illinois

CHICAGO—The Waterway Paper Products Co., Kedzie Ave. and 32d St., has commenced the erection of its proposed new plant at location noted, consisting of a main 1-story building, 80 x 180 ft., with power plant, 33 x 60 ft., estimated to cost about \$200,000, with machinery. Frank D. Chase, Inc., 645 Michigan Ave., is architect and engineer.

Indiana

VINCENNES—Fire, Oct. 11, destroyed a portion of the flour-milling plant of the Atlas Mills, with loss estimated at close to \$200,000, with machinery.

Maryland

FROSTBURG—The Big Savage Brick Co. has commenced the erection of a new drying department at its plant and will soon inaugurate operations for other extensions, estimated to cost about \$85,000. D. A. Benson is manager.

BALTIMORE—The Spanish-American Cork Products Co., Westport, near Baltimore, is planning for the immediate rebuilding of the portion of its local plant on Fish House Road, recently destroyed by fire with loss of about \$75,000. O. J. Harms is president.

Massachusetts

SOMERVILLE—Masury, Young & Co., 196 Milk St., Boston, Mass., manufacturer of oil products, etc., will equip a portion of its new 3-story building now being erected on Rollins St., Somerville, 35 x 75 ft., as an oil-testing works.

CHELSEA—The United Indigo & Chemical Co., 960 Broadway, will commence the immediate rebuilding of the portion of its plant recently destroyed by fire, with cost estimated at \$21,000. John Cowen is superintendent.

Michigan

DETROIT—The Detroit Sand Lime Brick Co., 507 Vinton Bldg., will soon take bids for the erection of its proposed new plant. Plans are nearing completion.

New Hampshire

HINSDALE—Fire, Oct. 5, destroyed a portion of the paper mill of the G. A. Robertson Co., with loss estimated at close to \$100,000, including machinery.

New Jersey

JERSEY CITY—The Apex Color Works, Inc., 61 Cornielson Ave., has completed plans and is taking bids for the erection of a new 1-story plant, 50 x 100 ft., on Van Winkle Ave., estimated to cost about \$22,000. Edward Patterson, 76 Montgomery St., is architect.

WOODSTOWN—The South Jersey Farmers' Exchange is considering tentative plans for the erection of a new local plant for the manufacture of fertilizer products.

BAYONNE—The Standard Oil Co. of New Jersey, 26 Broadway, New York, is arranging an appropriation of \$2,000,000, for extensions and improvements in its three refineries in this section, comprising the Constable Hook works at Bayonne; the Eagle Works at Jersey City, and the Bayway plant at Elizabeth. Walter C. Teagle is president.

New York

LONG ISLAND CITY—A. L. Reade & Co., 141 West 36th St., New York, manufacturer of celluloid specialties and novelties, has leased the 2-story brick building now being erected on Ely Ave., near the Bridge Plaza, Long Island City, for a new plant.

BUFFALO—The Buffalo Specialty Co., 375 Ellicott St., is said to be planning for the rebuilding of its plant at Bridgeburg, Ont., destroyed by fire, Oct. 13, with loss estimated at about \$50,000.

BUFFALO—The Niagara Gas Corp., 186 Main St., has preliminary plans under way for the erection of a new gas filtration and purifying plant at South Buffalo, in the vicinity of the works of the Donner Union Coke Co., estimated to cost about \$350,000. The company recently took over the artificial gas plant of William J. Judge, and has increased its capital to \$4,000,000.

Pennsylvania

POTTSTOWN—The Hydro United Tire Co., manufacturer of automobile tires, has awarded a contract to Graham & Wells, 3649 Filbert St., Philadelphia, Pa., for the erection of a 2-story plant addition, 134 x 170 ft.

EASTON—The Forbes Aluminum Products Co., Steele Bldg., has awarded a contract to the R. T. & C. D. Stewart Construction Co., 26 Center Sq., for the erection of its new plant in the South Side section, to consist of a number of buildings of various size, estimated to cost about \$150,000. Later proposed extensions will bring the ultimate investment to close to \$500,000. The company was incorporated recently under Delaware laws with capital of \$4,500,000. Ewing M. Forbes is president. A. D. Chidsey, Jr., 341 Northampton St., Easton, is architect and engineer.

BETHLEHEM—The Travelers' Rubber Co. will install new machinery at its plant for increased production, estimated to cost about \$30,000.

NEW BRITGTON—The Townsend Co., manufacturer of iron and wire products, has construction under way on a new wire mill on Fallston Ave., occupying a large portion of a 3-story building, 124 x 128 ft.

South Carolina

COLUMBIA—The Halo Co., recently organized with a capital of \$400,000 to manufacture extracts, has plans under way for the erection of a new local plant, 50 x 140 ft. Bids will be asked in about 60 days. E. M. Lowman is secretary.

Tennessee

MEMPHIS—The Memphis Cotton Seed Products Co., recently organized, has acquired a local site for the erection of a new mill. Preliminary plans are under way. A. G. Roberts is president.

MEMPHIS—The Stryker Kot-N-Wood Products Co., has acquired local property as a site for its proposed new mill, 60 x 200 ft., for the manufacture of plaster-board products from cotton stalks. The machinery installation will include hydraulic presses, digesters, shredders, mixers, etc. Other plant unit will be constructed at a later date. George B. Stryker is president.

KNOXVILLE—The Knoxville Pure Paint & Varnish Co., recently formed with a capital of \$150,000, has awarded a contract to Worsham Bros., Knoxville, for the erection of a 2-story and basement plant, 50 x 125 ft., for the manufacture of paints, oils, varnishes, etc., estimated to cost about \$32,000. J. R. Lee is president and J. C. Trewitt, vice-president.

Texas

DALLAS—The Dallas Oil Refinery Co., 3131 Oak Lane, has preliminary plans under way for the erection of a new oil-refining plant on local site.

SAN ANTONIO—The Grayburg Pipe Line Co., Grayburg Bldg., has awarded a contract to J. S. Young, Somerset, Tex., for the construction of a new oil works, estimated to cost about \$40,000 and of which the machinery installation will represent about \$25,000.

DALLAS—In connection with the remodeling of the plant of the Eastland Oil & Refining Co., recently acquired, the Trinity Oil Corp. has tentative plans under way for the erection of a new lubricating oil manufacturing plant on an adjoining site. Harry Pennington, Oklahoma City, Okla., is president; J. W. Rieker, Dallas, is manager.

DALLAS—The Fleischmann Yeast Co. has arranged for the erection of a new 2-story building, to be occupied under lease, 50 x 115 ft., estimated to cost about \$30,000. It will be equipped for the manufacture of yeast products. Headquarters of the company are at 701 Washington St., New York, N. Y.

Virginia

PORTSMOUTH—The Chesapeake Mfg. & Creosoting Co., Money Point, near Portsmouth, is reported to be planning for the rebuilding of the portion of its plant, recently destroyed by fire with loss estimated in excess of \$200,000.

West Virginia

HUNTINGTON—The Camp Glass Co., Twenty-fifth St., is planning for extensions and improvements in its plant to cost about \$30,000. The company is operated by the Interstate Glass Co., Bradford, Pa. Daniel Camp is manager.

STAR CITY—The Star Glass Co. has awarded a contract to the Pittsburgh Bridge & Iron Works, Farmers' Bank Bldg., Pittsburgh, for the erection of a new plant to total about 60,000 sq. ft. of floor space. The structure will be equipped for the manufacture of illuminating glassware products.

New Companies

THE RUSH PORCELAIN Co., Room 1922, 24 Archer Ave., Chicago, Ill., has been incorporated with a capital of \$40,000, to manufacture porcelain products and kindred specialties. The incorporators are Charles G. Rush, H. Jones and L. L. Cowan.

THE REGAL MFG. Co., Kansas City, Mo., has been incorporated under Delaware laws with capital of \$200,000, to manufacture chemicals, insect powders and affiliated specialties. The incorporators are Ray M. and H. L. Dunnett, and Frank D. Auwarter,

Kansas City. The company is represented by the Corporation Service Co., Wilmington, Del.

GEORGE H. CLARK & Co., INC., Worcester, Mass., has been incorporated with a capital of \$32,000, to manufacture paints, oils, etc. George A. Clark is president; and Harry A. Clark, 25 West St., treasurer.

THE INSTANT CHEMICAL MFG. Co., New York, N. Y., has been incorporated with a capital of \$250,000, to manufacture chemicals and affiliated products. The incorporators are F. M. Dunn, J. L. Nichols, and Guernsey Price, 1 Liberty St.

THE GEM FOUNDRY Co., Muskegon, Mich., has been incorporated with a capital of \$10,000, to manufacture brass, aluminum and other metal castings. The incorporators are Harry J. Pangburn, Samuel Feltman and Jacob A. Poupstra, Muskegon.

THE HOWARD FINISHING Co., Meriden, Conn., has been incorporated with a capital of \$50,000, to manufacture glassware, porcelain products and kindred specialties. The incorporators are J. L. Howard, Meriden; W. J. Howard, Hartford, Conn.; and J. J. Howard, New Haven, Conn.

THE JUST SOAP MFG. Co., INC., Kearny, N. J., has been incorporated with a capital of \$25,000, to manufacture soaps, washing powders, etc. The incorporators Jacob B. Cohen, William M. Grant, and Lovett A. Grant, Lincoln Highway, Kearny.

THE UNITY UTILITIES CORP., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture rubber products. The incorporators are W. B. Sorrelle, H. A. Jacobson and L. J. Annen. The company is represented by H. P. Freese, 27 William St.

THE ILLINOIS-WYOMING OIL Co., 2135 West 72d St., Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture oil products. The incorporators are John F. Stoner and Frank A. Foltz.

THE PROVIDENCE BRASS REFINISHING Co., 47 Mill St., Providence, R. I., has filed notice of organization to manufacture brass, bronze and kindred metal products. William Carroll, 175 Hoyt Ave., Rumford, R. I., heads the company.

THE FEDERAL CARBONIC GAS Co., Jersey City, N. J., has been incorporated with a capital of \$500,000, to manufacture carbonic gas and other commercial gas products. The incorporators are Frank E. Taylor, Thomas J. Burke and R. Emmett Sullivan, 57 Randolph Ave., Jersey City.

THE WALKER LUBRICATING OIL & REFINING CORP., New York, N. Y., has been incorporated under Delaware laws with capital of \$2,000,000, to manufacture refined oil products. The incorporators are T. B. and W. D. Walker, and John J. Ford, New York. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington, Del.

THE FORT MCCOY TURPENTINE Co., Fort McCoy, Fla., has been incorporated with a capital of \$40,000, to manufacture turpentine and kindred products. W. J. Wilson is president, and J. H. Burroughs, secretary and treasurer, both of Fort McCoy.

THE AURORA LEATHER Co., 6030 South State St., Chicago, Ill., has been incorporated with a capital of \$15,000, to manufacture leather products. The incorporators are Abraham Sohn and N. S. Wolf.

THE WELNESS PAINT Co., New York, N. Y., has been incorporated with a capital of \$10,000, to manufacture paints, varnish, etc. The incorporators are P. J. Welch, B. W. and T. F. Guinness. The company is represented by D. F. Griffin, 44 Court St., Brooklyn, N. Y.

THE DOSCH CHEMICAL Co., Wilmington, Del., has been incorporated under Delaware laws with capital of \$2,500,000, to manufacture chemical products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE IOTLA CLAY & MICA Co., Iotla, N. C., has been incorporated with a capital of \$50,000, to manufacture clay products, mica goods and kindred specialties. The incorporators are Herman A. Gudger, Asheville, N. C.; A. W. Mangum, Chapel Hill, N. C.; and Francis A. Gudger, 469 Fifth Ave., New York, N. Y.

THE GARY PAINT Co., Gary, Ind., has been incorporated with a capital of \$10,000, to manufacture paint, varnish, oils, etc. The incorporators are Edward Jacob, C. W. Stilwell and W. A. Elliott, Gary.

THE TANLAC Co., Dayton, O., has been incorporated under Delaware laws with capital of \$50,000, to manufacture chem-

icals and chemical byproducts, drug specialties, etc. The incorporators are L. N. Conrad, J. B. Coolidge and J. J. Gibson, all of Dayton. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE ANCHORS CHEMICAL & DYE WORKS, East Orange, N. J., has filed notice of organization to manufacture chemicals, dyes and affiliated products. The company is represented by Elwood B. Hendricks, 645 Springdale Ave., East Orange.

THE CUMBERLAND COUNTY REFINERY, INC., Burkesville, Ky., has been incorporated with a capital of \$10,000, to manufacture refined oil products. The incorporators are Ernest J. Schabelitz, Burkesville; and Robert H. Wise, Waynesboro, Pa.

THE COLUMBIA CHINA CORP., Porter, Ind., has been incorporated with a capital of \$500,000, to manufacture chinaware and other ceramic products. The incorporators are J. R. Mendelson, E. T. Morris and L. I. Sutterman, all of Porter.

THE RED STAR LABORATORIES Co., 3256 Franklin Blvd., Chicago, Ill., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are R. A. Murphy, William R. Swisler and G. W. Andrews.

THE LAWRENCE OIL Co., INC., Norwood, Mass., has been incorporated with a capital of \$350,000, to manufacture oil products. Herbert Brady is president, and Ernest H. Grant, 83 Vernon St., Norwood, treasurer.

THE PENN RUBBER BALL CORP., Philadelphia, Pa., has been incorporated with a capital of \$5,000,000 under Delaware laws, to manufacture rubber products of various kinds. The company is represented by Frank R. Hansell, Land Title Bldg.

THE FISK OIL Co., Schenectady, N. Y., has been incorporated with a capital of \$200,000, to manufacture oil products. The incorporators are M. G. and J. F. Hocker, and H. A. Bradshaw. The company is represented by D. B. Sammon, attorney, Schenectady.

THE HUDSON COUNTY LEATHER & SUPPLIES Co., West Hoboken, N. J., has been incorporated with a capital of \$50,000, to manufacture leather chemicals and kindred supplies. The incorporators are P. Coniglio and Frank Valvano, 118 Summit Ave., West Hoboken.

THE KEYSTONE REFRACTORIES Co., Minneapolis, Minn., has been incorporated with a capital of \$600,000 under Delaware laws, to manufacture firebrick and other refractory products. The incorporators are H. B. Finch, W. K. Nash and C. R. Wilson, Minneapolis. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington, Del.

THE UNITED STATES AUTO PAINT Co., 20 Warrington St., Providence, R. I., has filed notice of organization to manufacture paints, etc. R. Gighotti heads the company.

THE EDWARDS PETROLEUM Co., Los Angeles, Cal., has been incorporated with a capital of \$250,000, to manufacture petroleum products. The incorporators are H. L. Edwards, C. H. Webb and R. M. Galbreth, 607 Citizens' National Bank Bldg., Los Angeles.

THE ATLANTIC EXTRACT Co., Boston, Mass., has been incorporated with a capital of \$10,000, to manufacture extracts, compounds, etc. Martin M. Leibell is president, and Nathan Rubin, Chelsea, Mass., treasurer.

THE CEMENT TILE & PRODUCTS Co., Wilmington, Del., has been incorporated under state laws with a capital of \$100,000, to manufacture tile and affiliated products. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE T. C. OIL Co., Montgomery, Ala., has been incorporated with a capital of \$200,000, to manufacture petroleum products. The incorporators are T. C. Hadley, Montgomery; R. A. Cooper & W. A. McSwain, both of Columbia, S. C.

THE JURICH Co., New York, N. Y., has been incorporated with a capital of \$15,000, to manufacture paints, varnishes, etc. The incorporators are L. and T. O. Jurich, and C. Hattendorf. The company is represented by Charles Novello, 320 Broadway.

THE UNITED ZINC Co., 23 West Illinois St., Chicago, Ill., has been organized to manufacture zinc products. The company

is headed by Edward F. Mestling and Willis H. Huston.

THE PARDUE OIL CORP., Wilmington, Del., has been incorporated with a capital of \$5,000,000 under Delaware laws, to manufacture petroleum products. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE HARBOR REFINING Co., Long Beach, Cal., has been incorporated with a capital of \$1,000,000, to manufacture refined oil products. The incorporators are J. W. Tucker, J. S. Harper, W. A. Miller, Jr., and D. L. Akeley, all of Long Beach.

Capital Increases, Etc.

THE ANCHOR LEATHER Co., 1001 West Division St., Chicago, Ill., has filed notice of increase in capital from \$50,000 to \$300,000.

THE ATLAS CRUCIBLE STEEL Co., Dunkirk, N. Y., is arranging for a bond issue of \$4,000,000, and of which \$2,000,000 will comprise the initial distribution, to be sold at an early date.

THE CREPE-KRAFT Co., Newark, N. J., manufacturer of paper products, has filed notice of change of name to the Krepkraft Co. A new plant is now being established in a portion of the former works of the Universal Caster & Foundry Co., Jackson Ave.

THE REFINING & ASSAYING CORP., 40 West Broadway, New York, N. Y., has filed notice of dissolution under state laws.

THE CRYSTAL CHEMICAL Co., organized under New York laws to manufacture chemicals, has filed notice of organization to operate in New Jersey. Charles Kanter, 747 Broad St., Newark, N. J., is representative.

THE PHILLIPS PETROLEUM Co., 115 Broadway, New York, N. Y., operating oil refineries, has arranged for a bond issue of \$3,500,000.

THE ELECTRIC ALLOY STEEL Co., Youngstown, O., is arranging for a preferred stock issue to total \$750,000.

THE BLUE RIDGE PAINT & COLOR Co., Allentown, Pa., has been adjudged an involuntary bankrupt. John G. Diefenderfer is referee.

Coming Meetings and Events

ACADEMY OF POLITICAL SCIENCE will hold its forty-first annual meeting at the Hotel Astor, New York City, Nov. 4 and 5.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

INDUSTRIAL COST ASSOCIATION will hold its second national conference at Pittsburgh, Pa., Nov. 2-4, with headquarters at the William Penn Hotel.

INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA will hold its annual convention at the Waldorf-Astoria, New York, Nov. 1-5.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society regular meeting.

Recognizing Our Organic Chemical Industry

AN EVENT of historical importance to the chemical industry occurred in Washington last week at the meeting which resulted in the organization of the Synthetic Organic Chemical Manufacturers Association. This new economic factor carries with it more significance than the usual trade association, for it marks the union of all the elements which go to make up our organic chemical industry. The manufacture of pharmaceuticals, synthetic drugs, aromatic, photographic and other fine chemicals is to be recognized as essential, if not equivalent, parts of an industry of which dyes and intermediates are only an important branch.

The association has wisely selected Dr. CHARLES H. HERTY, editor of the *Journal of Industrial and Engineering Chemistry*, to be its first president. His vigorous enthusiasm and indomitable spirit have won for him a position second to none in the fight for the adequate recognition of American chemical industry.

Railroad Strike Is Called Off

BEATING an ignominious retreat, the railroad labor leaders decided on October 27 to call off the strike of the five railroad brotherhoods and thus relieve business of the apprehension under which it has labored for several weeks past. In explanation of their action, Mr. SHEPPARD, president of the Order of Railway Conductors, is reported to have recognized the fact that public opinion had discountenanced the strike and that the Government had decided to marshal all its forces against the strike, should it be called. Had he stopped at that explanation his words would have commanded the respect that is due a man who sees the light and acts accordingly, but he weakened his cause by his reported statement that the railroads had succeeded "in their misleading propaganda to the effect that we really would be striking against the Government." No sane man had ever thought otherwise.

One other phase of the strike cancellation, as reported in the daily press, will be worth remembering. It is stated that after reaching the decision to cancel the strike "all of the union men were smiling as they came out and many of them jocularly pushed and shoved each other down the stairs." A ghastly joke, indeed, that they had played on American business, causing disturbance, unrest, uneasiness and apprehension for weeks, only to yield at last to the authority which they should have respected in the beginning. One is forced to the conclusion that the leaders never intended to call the strike and that the vote was used only as a club to coerce the Government into meeting their demands. Labor leaders have only to continue to play this kind of joke on the American public to experience for themselves and followers the fate of the one who cried "Wolf! Wolf!"

How to Reduce Taxes

THE future of the coal-tar dye industry is, alas, in the lap of politics. We had hoped that it would forge ahead, establishing itself by its own merits; we watched with interest and enthusiasm the extraordinary achievements of American chemists, as they accomplished forty years' work within the space of five years, and we hoped that this great feat would speak for itself. Instead of this the industry has been made the butt of undeserved complaint. Sometimes it seems as though, as a sequel of war, people have gone to the dogs for their principles as well as for their habits of thought!

At the last count we had 213 concerns making coal-tar products and eighty-two making synthetic dyes in the United States. They are making today 90 to 95 per cent of the dyes needed and used. And they are good dyes, despite the fact that the markets are flooded with wares that fade out on almost any provocation. We have discussed this matter before, but let's repeat a little of it to bring out the facts. We buy, for instance, a pair of black socks, and when they come back from the wash they are a dirty greenish gray. The dealer, to whom we complain, regrets that he cannot guarantee goods colored with American dyes. Now there never was made any better sulphur black than is made right here in this country. But while sulphur black costs 20 cents a pound and direct black \$1.10, it is much cheaper to dye with the latter, because it requires scarcely any work to put it on. Sulphur black, on the other hand, must be developed on the fiber, and that takes time and labor; and wages are high in the dyehouses. So the owner of the goods while they are in process has them dyed by the cheaper method, and direct black will not stand laundering, but sulphur black, rightly applied, will. This holds true all the way down the line; it requires labor and handling and care to put the right dye on the goods so that it will hold. The value of the dye that goes on a single garment is negligible. The main cost is the labor of putting it on. The difference between the cost of wearing apparel with German dyes free of duty and under embargo is a small fraction of a cent on a pair of socks and a few cents on a suit of clothes or a woman's dress. And every dye is available to the dyer.

Suppose our license system or embargo were allowed to lapse, what would happen? The Interessen Gemeinschaft, or German Dye Trust, has packed up, awaiting shipment, immense supplies of dyes of all sorts. Within two weeks it can land in New York, in two ships, dyes to supply the American market for more than a year. It can pay any duties we want to impose, its costs are one-half to one-third of American costs and while Germany is poor the I. G. is rich. Just two weeks' privilege under any kind of a tariff will enable it to kill the American industry.

Well, what of it? Most people don't care very much where the dyes are made that color their clothes. Financially speaking the industry is not important. All the dyes used in the country in a year amount in value to only a few months' sales of the Woolworth 5 and 10 cent stores. The profits or losses of the dye manufacturers do not constitute a national issue. True, no industry requires so many trained chemists in proportion to its product, but even that scarcely touches public opinion. If chemists lose their jobs, so do others. Why worry? Why make such a fuss over this thing? Just a little patience, please, and we shall reach the core of the problem.

We are talking of reducing armaments, and LORD knows we all want big armaments and big armies and navies reduced. We are sick of war, although we have not yet learned to put aside that which above all other things leads to war, which is the spirit of anger and hatred and mistrust. There is so much hair-trigger wrath abroad on earth that no nation can afford to give up all thought of defense at this time, although the costs of defense are killing costs.

In the meantime, chemical warfare has arrived. Nobody likes it, but it is bound to endure because it is more effective than powder and ball. One battalion of well-trained C.W.S. troops with proper materials can utterly defeat a whole brigade. At the beginning of the great war there wasn't any such thing as chemical warfare and at the Armistice 55 per cent of the warfare was chemical. Agreements and treaties will not put an end to it, because the army that uses it against an enemy that does not will win. Efficiency counts.

Now we are struggling under a burden of taxation that is using up our substance, destroying initiative and halting progress, almost wholly because of military costs. And in this very dye industry we have a self-contained arsenal, available for the production of munitions of war, which does not cost the Government one penny, which pays taxes, which does not encourage warfare or make men want to fight, which in times of peace gives us only materials used in peace, but which is ever ready, in time of war, to produce such potential munitions that no nation will dare to attack us. It leads to greater relief from taxation than any measure now before the American people.

Facts and Fancies

About the Oppau Explosion

SIX WEEKS has elapsed since the Oppau disaster, but notwithstanding the extraordinary interest in this subject, the technical press both in this country and abroad has published surprisingly little in the way of a scientific explanation of this calamitous explosion. Chemists and engineers of all countries have studied closely the meager reports which have been published not only for what they contribute to our general knowledge of explosions but also because of the probable effect upon the German nitrogen industry. Explosive experts are especially concerned with the accounts of the nature of the damage and demolition and the distances at which the effects of the explosion were felt. Even the war yielded few if any examples of such tremendous disruptions from which comparable data and experiences could be gained. The catastrophe at Halifax resulting from the explosion of three million pounds of TNT involved only about one-third of the

mass of material reported to have exploded at Oppau. On other pages of this issue the reader will find an authentic report of the explosion prepared by one who had an unusual opportunity to study the scene of the disaster. With it are a number of excellent photographs, a careful study of which should prove of value in helping to gage the magnitude of the occurrence and to test the various theories regarding its possible origin.

The fact remains that little is known regarding the real cause of the explosion. The blasting of the caked material with dynamite, which to the uninitiated appears to be extremely hazardous, is common practice in ammonium-nitrate plants both in this country and abroad. Moreover, ammonium sulphonitrate, the mixed salt at Oppau, has always been regarded as non-explosive. The director of the Physikalisch Technische Reichsanstalt was unable to explode the material except when it was tightly packed in iron pipe and given an unusually violent detonation. Recent experiments conducted in this country with crystallized NH_4NO_3 , $(\text{NH}_4)_2\text{SO}_4$ and with intimate mixtures of the two powdered salts tend to confirm this supposition.

The theory of the spontaneous decomposition of the salts, which from the chemists' point of view is at least within the realm of possibility, is regarded as purely speculative by some of the foremost explosive experts. One circumstance, however, which appears to strengthen the argument in favor of this theory is the report that on the night preceding the explosion certain observers had noted a change in color and a slight rise in the temperature of the mass. The bursting of one of the synthetic-ammonia catalyzers, which at first was hailed as a most likely explanation of the preliminary and detonating explosion, is now almost entirely discredited by the photographs showing so little damage to the part of the plant in which the catalyzer bombs were housed.

Furthermore we are confronted with the fact that ammonium nitrate itself is something of a mystery. Those who know anything about powder plants cannot help recalling instances when it acted as it shouldn't. We are told that once upon a time, of twenty vessels working up ammonium nitrate, No. 6 and No. 18 suddenly exploded, demolishing several others. At the same instant some barrels of nitrate in a storage shed went off and only scattered holes in the ground were left to mark the places where they stood. Surrounding barrels were broken and charred, but did not explode.

A very plausible explanation of such an occurrence was to assume that a minute amount of some highly unstable impurity was located somewhere within two or three of the barrels and its peculiar sensitiveness was responsible for the explosion. At Oppau, however, the ammonia used was a synthetic product which should have been unusually free from pyridine and similar impurities contained in ammonia from byproduct coking plants. Nor should nitric acid made by the oxidation of this ammonia contain traces of nitrated cellulose such as are carried over in the spent acid commonly used in powder plants. These are circumstances which undoubtedly would have made for greater stability of the ammonium nitrate prepared from such materials.

Still another very puzzling question is to explain the means by which the explosion spread from one center to another. If we accept the contention that heat, rather than shock or pressure waves, is the primary cause of detonation, we are unable to account for the fact that there is practically no evidence of fire in the

spaces which separate the explosive centers, notwithstanding that much of the wreckage is apparently made up of timber and other flammable material.

It is easy, perhaps, to account for the fact that certain portions of the plant are relatively undamaged while across the river in Mannheim extensive destruction was reported. A phenomenon which has often been noted in connection with large explosions is that the rush of air appears to take a wave-like course, harmlessly passing over one district only to dip down at some distance and wreck havoc with all that comes in its path. This, too, explains why observers in different localities will often report conflicting views regarding the relative intensity of two explosions.

To summarize what we know and don't know about the explosion is a difficult task, but it is certain that much remains to be learned. A scientific review of the facts reported from the scene of the catastrophe and an intensive study of the nature of ammonium nitrate and its mixtures may not explain all of the mysteries of the Oppau explosion, but it will do much to prevent the recurrence of similar disasters.

Earnings in the Steel Industry

THE financial report of the United States Steel Corporation for the third quarter of 1921 is very gratifying from the economic viewpoint, since it shows that it will be possible to cheapen the price of steel still further in the future and thus broaden the opportunity for its use. Wall Street regards the report as "bad, but not nearly as bad as expected."

Estimates made from time to time indicate that the Steel Corporation's shipments of steel products for sale in the September quarter amounted to about 1,200,000 tons, so that with earnings reported of \$18,918,058 the earnings were about \$15.75 per ton. Shipments averaged only about 30 per cent of capacity, and the earnings were small on that account, not on account of the rate per ton.

Already steel prices make a very fair comparison with pre-war levels, but every dollar a ton reduction will help broaden the demand for steel in future years. On a weighted average, steel prices now are about 28 per cent above the ten-year pre-war average, 34 per cent above the average of 1913 and 63 per cent above the low point of December, 1914.

It is true that independent steel companies have lately been showing large losses, in contrast with the Steel Corporation's profits. The statement frequently made that the Steel Corporation has a great "advantage" over the independents does not provide an explanation for this divergence. The Steel Corporation's inherent advantage is not large per ton, and it existed in 1912 and 1913, when the independents made profits although the Steel Corporation's earnings were \$10 per ton against \$15 per ton last September or in the September quarter. The explanation rather is that in 1920, when the independents advanced prices freely while the Steel Corporation held its prices down, the independents acquired expensive habits, which must be shaken off. Then there is probably a difference in that the Steel Corporation made radical allowances for excess inventory valuations in 1920, while the independents may have left some of that adjustment for this year. Another factor affecting comparisons at present is that in recent months the Steel Corporation has had a

heavier operation than the independents, by reason of good will acquired by the price limitation policy of 1920.

Altogether, the outlook for steel supplies in the future at really very moderate prices is greatly improved.

Social Stepping

A Business Necessity

NOW the season of increased human sociability approaches. Michigan Boulevard squaws, corner grocery habitués, statesmen, working girls, fishermen, profiteers, flappers, engineers, bathers and chemists will soon be forced to spend more time indoors and partake with different degrees of enjoyment of interior recreations. And it is well that nature so orders, for there is a very serious side to the seeming lightness of social frolicking. Social contact with fellow humans has more to do with the success of the individual than the same amount of time spent grinding at work without respite. This applies to personal development and business progress alike.

There is a chap who was so puritanical in his youth that he preached to his high school class against dancing at parties. A kindly old lady took stock of him in his first year at college and talked him into getting a girl and a dress suit. This chemist has never lost his appetite for hard work, but is now so filled with gregariousness that he will travel across the continent to a convention if dancing is among the listed events. He has broadened into a well-poised successful engineer.

EDISON has long been reputed as an inveterate worker, yet we find him in his later and we hope wiser years associating with men in other walks of life. Had he stepped away from the bench occasionally during his earlier years the general philosophy he now propounds would be less ingenuous, more sound. Litterateurs and artists have long dealt with society as a medium for their business activity. Observation of other men's motives has always been their stock in trade. Our more successful scientists count heavily as social bears. Chemists' clubs in Chicago, New York and elsewhere have the community's progressive men of science most active in social affairs.

In past years some scientists have succeeded in spite of their secluded lives, but never because of uninterrupted work within their cells. Since success in chemistry is becoming more a question of industrial application and less a matter of mystifying the public, the individual chemist must develop into a social mixer. As the business man would put it, he must sell himself through his personality and purchase current knowledge with discrimination. Ability to discriminate between buncombe and truth is an art most easily acquired by close study of the human vender. Secluded preachers are easy marks for book agents and overstudious truthseekers soft stuff for blue-sky salesmen, for both types lack experience in reading human character.

Application at the wheel without respite will only grind the rut deeper. Accomplishment of the artisan's task requires that the cutting tool move forward after the proper depth has been reached. Performance of organizations without wastage calls for co-ordination of efforts of all the separate parts. Human contact in a lighter vein is the best co-ordinator. Both the community and the individual profit if each one goes out stepping occasionally. This season is a good time for it.

Readers' Views and Comments

Impact Strength of Monel Metal and Aluminum Bronze

To the Editor of Chemical & Metallurgical Engineering

SIR:—Mr. Waltenberg's description of impact tests on Monel metal, on page 322 of your issue for Aug. 24, brings out very clearly the excellent resistance of this material to shock, but does not seem to do entire justice to other materials with which it might be compared. For instance, it might be expected that a metal with a ductility represented by 45 per cent elongation in 2 in. would have a greater impact resistance than metals with from 2 to 23 per cent elongation, yet these are the only metals on which impact figures are given in this article in comparison with Monel. In spite of the better shock resistance of the latter, it is doubtful if it will displace the heat-treated alloy steels of higher strength from many of their present applications.

Aluminum bronze, however, is an alloy with which Monel metal might well be compared, and some impact results on this alloy would have been of more practical interest in this connection. Reference might be made for this purpose to a "Study of Impact Tests on Alloys," published by A. B. Wilson on page 616 of *The Foundry* for Aug. 1, 1920. Unfortunately the nearest approach to Izod or Charpy tests that he reported are Fremont tests, where the cross-section area of the specimen at the notch was only 10 x 7 mm. instead of 10 x 8 mm., as in Mr. Waltenberg's tests. The extra millimeter in thickness would have a disproportionately greater effect on the results in this test in favor of the Monel metal, so a strict comparison is impossible. But even under these adverse conditions, and on cast material, a figure of 88.4 ft.-lb. was obtained for aluminum bronze, which is higher than that for any of the steels quoted by Mr. Waltenberg. Under the same conditions this figure would undoubtedly approach or surpass the showing of cast Monel metal; and well-annealed titanium-treated cast steel has given even higher figures than this.

The method given for determining the quality factor places a decided premium on the elongation at the expense of the tensile strength, so that Monel metal, with the highest elongation of any of the metals given, is bound to come out ahead. For instance, a common annealed brass would have by this method about the same high quality as the heat-treated nickel-chromium steel. The figures given here for aluminum bronze seem to be minima taken from a specification, instead of good average results like those for Monel metal. By referring again to Mr. Wilson's article mentioned above, it may be seen that proper comparative figures for cast aluminum bronze would be 80,000 tensile strength and 35 per cent elongation, giving a quality factor of 1,167 instead of the 875 obtained from Mr. Waltenberg's figures. This would place aluminum bronze above all but one of the steels, which is about where it belongs in a "quality" comparison of this kind. And it should also be remembered that the figures I have given above are for cast aluminum bronze, and thus subject to more or less improvement by skillful mechanical work.

Recovery of Volatile Solvents by the Bregeat Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—My attention has been directed to the letter of Messrs. Roulleux and Dort, in your Aug. 3 issue, in reply to a letter by James C. Lawrence, in your July 20 issue.

As a rule I do not think anything is gained by entering into controversy, but there are several statements in the former letter to which I feel it my duty to take exception, particularly the following: "Until the Bregeat process had been developed solvent recovery was not an industry by itself. The Bregeat process is responsible for bringing solvent recovery out of the class of an incidental and casual art into that of an independent and well-established business." This statement ignores altogether the work done by the Scott Co. which for twenty years has been making and installing solvent recovery apparatus. These installations have been furnished to prominent firms throughout the world for various industrial purposes, whereas the Bregeat plants tabulated in the article published in your issue for May 25 were chiefly, if not wholly, for war-time purposes, installed when expense was not an item to be considered. The number of installations made by the Scott Co. during the last twenty-odd years speaks for itself regarding the work of that firm in developing solvent recovery. The fact that up to the present time British manufacturers have been the largest users of solvent recovery apparatus for industrial purposes and that these installations have been built mainly by British firms is sufficient evidence of where the process has been largely developed.

Studies in Colorado Shale Oils

To the Editor of Chemical & Metallurgical Engineering

SIR:—On pages 452 and 453 of your Sept. 7 edition appears an article written by Arthur J. Franks in which he makes a statement that for the determination of sulphur, "the peroxide fusion method does not require more time and energy than the oxygen bomb method." My experience in this work has been that considerably more time is required to determine sulphur by the fusion method than by the use of the oxygen bomb washings. The bomb that I have been using is the standard oxygen bomb furnished with the Parr oxygen bomb calorimeter and is equipped with a rubber gasket. I agree with Mr. Franks that when a lead gasket is used some extra time will be required. However, recent determinations made in our laboratory have proved conclusively to me that as far as the time element is concerned the advantage lies in favor of the oxygen bomb method. The results of these determinations, as well as many others I have run, show that more consistent results are obtained by the use of the fusion method, that slightly lower results are given by the oxygen bomb determinations, and as stated before, that much time is saved by using the oxygen bomb.

PAUL F. HOOTS,

Chemist, New Orleans Railway & Light Co.
New Orleans, La.

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENEVA, ITALY, Oct. 5, 1921.

SEPTEMBER was a very fair month for the Italian chemical and metallurgical industries, and the number of orders, together with a further rise in foreign exchange, kept prices high. In some cases, especially with goods of foreign importation, there was an increase in price. The greater part of the business remained in the hands of French and German exporters owing to the lower rate of exchange in France and Germany compared with that of the United States and England.

ITALIAN POTASH MINES

The Italian firm Società Mineraria Coloniale Italiana, of Massaua, possesses potash mines capable of producing, when worked under normal conditions, from 5,000 to 8,000 tons per month of potash material. These mines are located in Abyssinia close to the Eritrea frontier, and the mineral is transported to Massaua (Italian Eritrea Colony) in part over land and in part by water through the seaport of Marsa Fati-mari. The firm employs, when working full time, more than 1,000 persons, most of whom are natives. In 1917 one-half of the production of the mines was sent to Italy, two-sevenths to France, one-seventh to England and the rest to Egypt. The Italian who discovered the mines in 1911 obtained from the Abyssinian Government a concession for their exploitation for thirty-five years.

ITALIAN SULPHUR INDUSTRY

The crisis in the Sicilian sulphur industry led to several meetings at the Ministry of Industry at Rome, where the representatives of the miners and the workmen insisted that no reduction of present wages should be enforced, as the cost of living has recently increased. The Consorzio Obigatorio per l'Industria Zolfifera Siciliana insisted on the necessity of its being authorized to conduct the refining of sulphur on its own account, or on the authorization to have refining conducted on its own products by the refineries already working. This position is easily understood when it is considered that exportation of refined ground sulphur increased during the first four months of the year to 15,887 tons, from 12,202 tons in 1920 and 5,951 tons in 1919 during the corresponding months and the exports of flowers of sulphur during the same months were 4,406 tons, against 6,921 tons in 1920 and 4,171 tons in 1919. There was also much discussion on the grinding of sulphur, the Sicilian producers giving an idea of the loss caused by this being conducted outside the island of Sicily.

NEW COMMERCIAL CONVENTION

A new commercial convention has been arranged with Poland for an exchange of products between the two countries despite the drastic exportation and importation prohibitions. The convention will continue in effect for six months. An agreement for nine months has also been arranged with Germany by which Italy will facilitate the importation of the following products: Synthetical essential oils and products, explosives, gelatine, coal-tar colors, colors for printing, colors for paints, articles of perfumery with and without alcohol, toilet soaps, lubricants and combustible mineral oils.

Germany consents to the importation of lemon oil, orange oil, bergamont oil, lavender oil, peppermint oil, and other natural essential oils, citric acid, tartaric acid, oleic acid, liquid and solid tanning extracts, licorice extract, glycerine, talc, citrate of lime, pumice stone, raw boric acid, clove oil, seed oils, washed industrial olive oil and sulphide green olive oil.

ITALIAN ESSENTIAL OILS

The Agricultural Federation of Western Liguria has formed several organizations, among other places at Carpasio, Porto Maurizio, for the distillation of aromatic flowers and plants, and is encouraging the substitution of modern plants working with steam for the old Arab apparatus of the Middle Ages using direct fire. The federation is also encouraging the cultivation of aromatic plants. Fields have been placed at its disposal at San Remo, on the Riviera, where experimental cultivation will be carried on. At Porto Maurizio capitalists are projecting the establishment of a large plant for the extraction of the essence of roses and other flowers and plants to produce natural perfumes and aromatic products. During 1920 Italy exported 2,539 tons of fresh flowers, in 1919 2,109 tons and in 1918 1,163 tons.

ITALIAN MANNA PRODUCTION

Italy is the only country in the world where the manna plant is utilized for medicinal purposes, although it grows as a tree also in other portions of Europe and in America. Castelbuono, in Sicily, is the principal center of the manna tree cultivation, nearly two-thirds of the entire Italian production being collected there. For this reason there has been established at Castelbuono an experimental station for the growing of the manna tree. The cultivation of some new species will be essayed and the various species of manna will be classified according to their botanical origin and their physical characteristics. Their employment in the different industries will be studied and an attempt will be made to intensify their use in pharmacy. Their therapeutic effects will be closely studied in relation to other pharmaceutical products of analogous properties of nature. Besides this, the chemical characteristics of the various adulterations will be investigated, as well as control of prices.

ELECTRIC RAILWAYS IN ITALY

The general director of state railways has proposed to the Italian Government that Germany be made to deliver, on account of war reparation, a certain quantity of electrical materials, not obtained quickly enough in Italy itself, for the electrification of the most urgently needed electric lines. It has been proposed to electrify the Pisa-Leghorn and Brennero-Verona-Bologna lines and those in the Istrian peninsula and Trento district. Express service is also being considered between Rome and Naples. Projects are also being studied for the electrification of the Naples-Reggio-Calabria and Paola-Cosena lines. For this vast system of electrification 90,000,000 lire has already been obtained.

ITALIAN PRODUCTION OF MINERALS

The quantities in tons of ores mined in Italy during the past year were: Iron, 473,000; manganese, 29,140; copper, 6,360; lead, 34,425; zinc, 73,180; silver, 500; antimony, 125; iron pyrites, 316,500; iron-copper pyrites, 4,400; and metallic mercury, 855.

A PARTIAL VIEW OF THE WRECKAGE CAUSED BY THE OPPAU EXPLOSION

The Explosion of the Nitrate Plant at Oppau

Some Interesting Comments on the Disastrous Effects and the Possible Causes of the Fatal Explosion at the Plant of the Badische Anilin und Soda Fabrik at Oppau, Germany, on Sept. 21, 1921

UNUSUAL interest attaches to the serious explosion which wrecked a large part of the extensive chemical works at Oppau, Germany, caused much damage to the surrounding country and was responsible for the deaths of hundreds of employees. Although a number of theoretical explanations have been proposed, the fact remains that little is known, or probably ever will be known, regarding the true origin of the explosion. In the following pages, however, there is presented an interesting report of a German chemist and engineer who was in the region at the time and later inspected the scene of the disaster. There are also included a number of unusual photographs, which when carefully studied in connection with the accompanying map, clearly reveal the extent and nature of the damage caused by the explosion.

First-Hand Impressions of the Oppau Disaster

BY DR. ING. CARL COMMENTZ

It was the privilege of the writer to inspect the Oppau plant of the Badische Anilin und Soda Fabrik on Sept. 29, 1921, or a little more than a week after the fatal explosion which so completely destroyed this important center of German chemical industry. Words cannot picture the extent of this destruction and even the photographs which accompany this article give but a limited conception of the almost inconceivable wreckage caused by the sudden explosion of about 4,500 tons of the practically unknown chemical fertilizer ammonium sulphonitrate. The explosion itself is a mystery and very probably will remain so, for apparently no one was aware of any unusual danger incident to the manufacture and storage of this chemical product.

THE STORY OF THE EXPLOSION

The story of the terrible disaster is a very short one. At 7:29 and again at 7:32 in the morning of Sept. 21, there occurred two terrific explosions in the northern

part of the plant, which is devoted to the production of ammonium nitrate and other salts. The large buildings containing the ammonium sulphonitrate disappeared entirely and nothing was left in their place except a mammoth crater 250 ft. in diameter and more than 50 ft. in depth. This crater filled with water immediately after the explosion, so that its apparent depth is somewhat deceiving. (See Figs 1 and 2.)

No one of the workmen in or near this part of the plant escaped and there is none left to give an account of what immediately preceded the explosion. In all 430 lives were lost and included in this number are over 200 whose bodies had not been recovered even after a week of diligent search. General work had not yet begun at the time of the explosion and of the 7,000 employees only about 2,225 were at the works.

The village of Oppau, surrounding the plant on three sides and inhabited mostly by its workmen, suffered great damage. Over 70 per cent of the thousand dwell-

FIG. 1. A VIEW FROM THE EDGE OF THE CRATER CAUSED BY THE EXPLOSION

FIG. 2. LOOKING SOUTHEAST FROM THE SCENE OF THE EXPLOSION. THE WALL STANDING AT THE RIGHT IS THAT OF ONE OF THE TWO STORAGE HOUSES

ings were either totally or partly wrecked. Most of the houses were occupied at the time and the fact that the loss of life in the village was comparatively small (only fifty were killed) is perhaps explained by the fact that in many cases the walls and roofs were sucked away rather than falling in or down upon the occupants. The damage to property in Oppau has been estimated at 175,000,000 marks.

EFFECTS ON NEIGHBORING DISTRICTS

Houses in the adjacent city of Ludwigshaven and in Mannheim, which lies opposite to Ludwigshaven on the right bank of the Rhine, were damaged, walls were shaken down and practically all windows were broken. At these places and at Heidelberg, which is about fourteen miles from Oppau, the effect of the explosion was first felt by two very heavy earthquake-like shocks. In Mannheim some seconds later and in Heidelberg 82 seconds after the shocks there came an enormous rush of air which broke windows and doors and caused damage to gas holders, oil tanks, and many river barges. The sound of the explosion and the earth shocks reached as far as Bayreuth, at a distance of 145 miles, and the air pressure wave caused considerable damage in Frank-

FIG. 3. DAMAGED BUILDING NEAR THE EXPLOSION

furt, which is about 53 miles from the scene of the explosion.

The process for the manufacture of the different salts from the synthetic ammonia was in operation before the outbreak of the war and two types of mixed salts were known—viz., the so-called “ammonsulfatsalpeter” ($(\text{NH}_4)_2\text{SO}_4 \cdot \text{NH}_4\text{NO}_3$) and the “kaliammonsalpeter” ($\text{K}_2\text{SO}_4 \cdot \text{NH}_4\text{NO}_3$). Although the former was the cause of the explosion, its production, handling and storing had never been regarded with suspicion, nor had it ever shown evidence of spontaneous ignition. Indeed, when stored in large quantities it forms itself into a hard, rocky mass and it has been common practice to blast the material with dynamite in order to prepare it for transportation.

THEORIES REGARDING THE ORIGIN OF THE EXPLOSION

No one will ever be able to give the exact cause of the explosion, but some facts which may have an important bearing on the subject were brought out in a recent discussion of the affair in the German Reichstag.

FIG. 4. A STREET IN THE VILLAGE OF OPPAU

It was said that the company intended to blast the material on a much larger scale in the near future, but it was not proved that this change had been put into effect. In past years about 16,000 blastings of the salt had been made with dynamite without any mishaps. Another cause which was spoken of is the reported explosion of a gas engine which gave a shock severe enough to detonate the large mass of mixed salt. It was also recorded that prior to the explosion the color of the salt was known to have changed from its usual pure white color to a slightly yellow color; and that the temperature in the storehouse had risen to 100 to 120 deg. F. during the night preceding the explosion. This would appear to strengthen the suspicion that by some sort of a decomposition there had been a spontaneous ignition of the mass.

EXPERIMENTS WITH THE MIXED SALT

The director of the Physikalisch Technische Reichsanstalt reported on experiments with ammonium sulphonitrate which had been made in his Institute directly after the catastrophe. A large number of unsuccessful attempts were made to explode this material, even with strong blasting dynamite cartridges such as are commonly used for mining purposes. However, using a very strong initial explosive and with the material packed into iron piping, the Institute succeeded in ex-

FIG. 5. DESTROYED HOUSES IN OPPAU

ploding a part but not all of the ammonium sulphate. Fire and high temperatures appear to have no exploding effect on this salt. The director concluded that nothing could be deduced from the experiments which might be said to have caused the explosion.

The management of the Badische company has announced that the manufacture of the salt will be abandoned at once and the ammonia will be used for the production of ammonium sulphate. The part of the plant in which the synthesis of ammonia was carried out is nearly intact and will require practically no rebuilding.

Ludwigshaven, Germany.

Evidence From the Photographs

EDITORIAL COMMENT

Several excellent photographs of the damage done by the Oppau explosion have now reached America. Some of them have been published in the newspapers, mostly using as subjects demolished residences in the town itself. The latter are of little technical interest, except that they bear evidence that much of the damage was done by violent expansion of the air within the dwelling, throwing debris into the streets and yards. This is a characteristic type of damage observed in the vicinity of heavy explosions. That the walls burst outward rather than collapsed inward is doubtless the reason the loss of life in the town was not far greater.

All trustworthy reports of the disaster agree that the damage was so extensive and violent that it could not possibly have been caused by anything but a large amount of solid or liquid explosive. It perhaps requires no argument to discredit early newspaper reports of a gas explosion; the airplane view in Fig. 7 shows a crater that would be expected from no less than thousands of tons of TNT. Comparison of this photograph with the map reproduced in Fig. 6 shows the

culprit to have been housed in the left of the pair of buildings marked "Ammonium Nitrate Plant," and the range of its destruction extended to the outer circle.¹

Some very interesting circumstantial evidence can be drawn from these two illustrations. In the first place, no disastrous explosion occurred in the material in the buildings marked "Storage"—either within that set of four long walls in the immediate foreground or the pair of arch roofed warehouses three tiers away. Second, the crater was excavated by a shock whose main effect was expended in a vertical cone. Note the way the upper ends of the walls of the storage buildings are trimmed off, also the way the near corner of the building at the left is shot away, leaving spindly steel columns standing near by. No great sidewise earth jar occurred, else the four tall smokestacks certainly would have collapsed. Third, there was more than one explosion. Note a small crater between the large one and the railroad grade to the right, where once a small unnamed building stood. A ragged trench appears to extend forward from the sulphuric acid concentrators, perhaps toward the narrow building shown in the extreme lower right hand corner of the map. If this is the result of a train of explosives, it may account for the total demolition, except for the foundations, of the building alongside. Protected as it was by the railroad embankment, it should not have been so completely razed by the main blast. Furthermore, a building

¹This map is adapted from that appearing in *CHEM & MET. ENG.*, vol. 24, p. 394, March 2, 1921, and was derived in the first instance from an article, bearing all the earmarks of authenticity, in *La Technique Moderne*, November, 1920.

FIG. 6. MAP OF THE WORKS AT OPPAU

devoted to the oxidation of ammonia at the extreme right border appears to have been demolished, possibly from an internal explosion, since nitric acid towers and pipe and conveyor trestles immediately alongside appear relatively unhurt. But most striking of all is the disappearance of buildings in the central portion of the area, marked in black on the map, and supposed to house apparatus for working up sodium nitrate. The fact that nitric acid at Oppau was made by the oxidation of synthetic ammonia makes it at least doubtful if sodium nitrate was being used or stored. It might even be possible that these buildings were being used as storage for ammonium nitrate. At any rate a relatively small space appears to have been swept clean by a blast which also went up, rather than sidewise, as can be inferred from the condition of neighboring pipe lines, conveyor galleries and gas-holders, and the litter of collapsed steel and wood immediately alongside to the right, shown in the photograph at the top of page 818.

WERE THE AMMONIA CATALYZERS RESPONSIBLE?

On the basis that the published map of the works is approximately correct, reasonable surmises as to the nature of the explosive are not forthcoming. Evidently gas could not do it. Nor would one expect that the amount of material in process, even in so large a plant as Oppau, if detonated could cause more than local damage. Yet the pictorial evidence is overwhelming in showing that the known storage buildings were not the seat of any explosions.

In view of the oft-repeated statement that ammonia catalyzers or converters burst at practically the same time as the main explosion, Prof. R. S. Tour of the University of Cincinnati expresses the opinion that this could have detonated large piles of "mischsalz" in the vicinity. He thinks that it may have been caused by the practice of injecting air into the synthetic ammonia converters for starting or to maintain temperature. The men at Oppau themselves realized that this was a dangerous practice, and made various attempts to develop operation so that this step could be avoided. Could this account for the isolated areas where excessive damage can be observed? The catalyzer building is so far from the observer in Fig. 7 that it is impossible to judge whether there was unusual destruction at that point—the front wall is gone, although the roof seems to be unharmed. Even though some of the catalyzers exploded, why should this have detonated material several hundred feet away? We are advised that explosions are caused by heat, rather than shock. And yet intermediate areas are covered with broken timbers—in fact, one of the peculiar things about the disaster is that it was not followed by fire.

One may object that the main crater cannot be explained by the bursting of chemical apparatus holding less than thousands of tons of the most violent explosive. On the other hand, neither ammonium nitrate nor the mixed salts (ammonium sulphate-ammonium nitrate) are usually regarded as explosive. Pure nitrate must be highly compressed and slightly heated before it can be detonated by a blasting cap. The commercial

FIG. 7. AIRPLANE VIEW OF OPPAU PLANT OF BADISCHE ANILIN UND SODA FABRIK
TAKEN AFTER THE DISASTER

salt cakes very easily, and it has been common practice to break large masses by dynamite when necessary to move it. Consequently it is fairly insensible to detonation. Intimately mixed with nitroglycerine, powdered aluminum or TNT, it was used extensively during the war as a high explosive, the two latter being commonly known as amonal and amatol. By the effects, one is tempted to suppose that it was some cellars full of this stuff which let go or perhaps even some forgotten mines prepared for the day when the Allied troops would appear along the Rhine!

Spontaneous Decomposition of the Mixed Salts

Dr. Ing. E. Hene of Stassfurt, in the Oct. 6 issue of *Chemiker-Zeitung*, suggests a gradual decomposition of the ammonium nitrate-ammonium sulphate mixture which might have caused the initial detonation of the Oppau explosion.

A possibility is suggested by the fact that one of the mixed salts—e.g., the sulphate—might have an acid reaction. The free sulphuric acid would liberate nitric acid from the ammonium nitrate, and this acid could react in various ways with the ammonium salts. For example, the following reactions are known:

- (1). $6\text{HNO}_3 + 5(\text{NH}_4)_2\text{SO}_4 = 18\text{H}_2\text{O} + 8\text{N}_2 + 5\text{H}_2\text{SO}_4 + 536 \text{ cal.}$
- (2). $2\text{HNO}_3 = 2\text{NO}_2 + \text{O} + \text{H}_2\text{O}.$
- (3). $\text{N}_2\text{O}_3 + (\text{NH}_4)_2\text{SO}_4 = \text{H}_2\text{SO}_4 + 3\text{H}_2\text{O} + 2\text{N}_2 + 138 \text{ cal.}$

It will be noted that in reaction 1 only 3 molecules of H_2SO_4 are required to produce the 6 molecules of HNO_3 , which react to regenerate not 3 but 5 molecules of H_2SO_4 . Furthermore, reactions 1 and 3 are exothermic. Hence under favorable circumstances it is possible for a small initial amount of free H_2SO_4 to produce a gradual increase of temperature and of acidity, thereby hastening the decomposition and eventually leading to detonation and explosion. Although the conditions may not seem to be favorable for reactions 1 and 3, it is possible that the pressure in the interior of storage piles, combined with the fact that the heat of reaction cannot be dissipated readily, may influence the reactions.

If these surmises are correct, it would seem that the addition of an alkali such as ammonium carbonate would be advisable. Large storage piles should be avoided and the piles should be turned over from time to time in order to prevent local overheating.

Production of Iron and Steel in Italy

The iron and steel industry in Italy, which succeeded in establishing itself in the pre-war period, reached its maximum activity during the war, but it has since rapidly declined, and it has suffered perhaps more than any other Italian industry from the present crisis. The principal cause of the difficulties encountered by the Italian industry lies in the high cost of fuel. In 1919, and still more in 1920, Italian iron and steel were produced at a cost 500 lire per ton in excess of the cost of foreign competitive products; and while the Italian industry was in this unfavorable condition, the home market was completely and freely open to importations from abroad, reports Consul General Osborne of Genoa in *Commerce Reports*.

Data in regard to the production, importation, exportation and apparent consumption of ore, pig iron, and finished iron and steel follow:

Silicate of Soda in Papermaking

BY JAMES G. VAIL

Chemical Director, Philadelphia Quartz Co., Philadelphia, Pa.

SILICATE of soda is a material which finds application in a great many branches of industry. Probably no heavy chemical has a wider range of uses. In its diversified application it has touched the experience of almost every one. Most papermakers are aware that it is used in the manufacture of paper and that it is added to the beater and precipitated with alum in the same manner as rosin size is precipitated, but only a small number know definitely the properties which its use imparts to paper. Some confusion is found also as to the respective functions of silicate of soda and rosin size in paper. Rosin size is necessary to give water resistance, but, as has been pointed out by Klemm¹ and others, resistance to printers' ink is produced with silicate of soda. A good deal of work has been done in the laboratory to show the nature of the precipitate which is formed from silicate of soda and the conditions under which this precipitate separates from the water in the beater and is retained among the fibers of the paper, modifying the character of the finished sheet.

The observations which are to be reported here are based also on practical experience with large quantities of paper. These have led to a better understanding of the behavior of silicate of soda in the beater and on the paper machine and have given a basis for better judgment of the conditions for its successful use.

NATURE OF SODIUM SILICATE

Before considering details of handling silicate of soda, it is necessary to make plain what we mean by this term. Silicate of soda is not the name of a definite salt, but rather the general name for an indefinite number of products composed of silica and soda in varying proportions. Different ratios of silica and soda, along with different concentrations of the solutions, give varying properties, both chemical and physical. It is this ability to modify the properties of silicate of soda which accounts for its great variety of uses. Adhesives, plastic cements, quick setting cements, sizings, gels, water softeners, detergents, paints and cements for digester lining are all included in its scope of usefulness. As drawn from the furnace, silicate of soda looks like glass. Like glass, the proportions of its ingredients may be varied within wide limits without much change in appearance. It differs from glass in that it may be dissolved in water. It comes upon the market in concentrated solutions. Much misunderstanding of results harks back to the assumption that silicate of soda is a definite thing, and many published articles report results which it is impossible to confirm or disprove without knowing just what grade of silicate of soda was used. Because two samples of silicate of soda look alike it does not follow that they are alike. Solutions ranging from 34 to 54 per cent total solids may have identical viscosity. The body of silicate is no index to the amount of solids present. To avoid confusion all manufacturers have established certain brands which represent definite compositions of silicate.

PRECIPITATION WITH ALUM

To precipitate silicate of soda in paper stock the soda is neutralized with alum. Hence a silicate with the

smallest possible amount of soda should be chosen for reasons of economy. The lowest alkalinity which is practical from a commercial viewpoint is represented by a solution containing 7 per cent total alkali as Na_2O and a ratio of soda to silicate approximating 1 to 4. A product of lower relative alkalinity is too nearly insoluble to be of commercial use. Failure to neutralize the soda completely will result in an imperfect precipitation on the one hand and injury to the rosin sizing of the paper on the other. A silicate of 1 to 2 ratio requires twice as much alum to produce a given effect on the paper.

A solution of the 1 to 4 ratio is a jelly at 37 deg. Bé. corresponding to 34 per cent total solids. When this is diluted to the concentration corresponding to that which obtains in the beater and a solution of alum is slowly added, the solution becomes more and more turbid until it becomes acid in reaction and a precipitate separates from the solution. Other precipitating agents, such as niter cake, calcium sulphate or even hard water, will precipitate silicate of soda, and when these are used the amount of alum added for the silicate can be proportionately reduced. This is a large factor in some mills. The precipitate is very bulky and light and readily becomes entangled with the fibers, assisting in their retention on the wire and cementing them together. If an insufficient amount of alum be added, no precipitation will occur and without precipitation the advantage of using silicate is lost. It is, therefore, of first importance to see that a sufficient amount of alum is used to give an acid reaction. The precipitate contains the elements of an aluminum silicate. It probably contains along with the aluminum silicate both aluminum hydroxide and hydrated silica. Silicate of soda thus differs from rosin size, which begins to precipitate when the first small quantity of alum is added.

TEXTURE DEPENDS ON DILUTION

The texture of a silicate precipitate depends on the dilution of the silicate and the alum. Under the conditions occurring in the beater a light flocculent product, well adapted to harden and increase the strength of the paper, is produced, but if the chemicals were mixed in relatively concentrated condition the material thrown out would be granular, sandy or lumpy, just as would be the case if dry alum were mixed with a strong solution of rosin size. When the light flocculent precipitate is dried, it hardens to a horny consistency, too hard to be crushed easily by the hand. In this hard condition it still retains a considerable amount of water, which contributes largely to its toughness. The apparently dry precipitate always contains at least 25 per cent of water under the conditions of drying paper.

RETENTION AFFECTED BY CONCENTRATION

The effect of retaining this material in the substance of paper is shown first of all by an increase in the ash of the paper. A study involving 550 tons of paper and an examination of 1,200 samples gave an average of 1 per cent in ash with an average addition of 3.48 per cent of liquid silicate based on dry fiber. The amount of dry alum necessary for the precipitation of the silicate was 25 per cent of the weight of the silicate solution. The average retention was 66 per cent of the total silica in the silicate, plus the Al_2O_3 of the alum. There is good reason to suppose that the use of larger proportions of silicate, as reported by Blasweiler,² would

¹Klemm, *Mineralische Leimung von Druckpapier*. *Wochbl. Papierfabr.*, 1907, No. 25, p. 1983.

²*Papierfabrikant*, 1921, vol. 33, p. 875.

not only produce more marked effects on the paper but would be accompanied by a higher percentage retention. Amounts as high as 10 per cent of the dry fiber will make the stock appreciably slower on the wire, but this effect was not observed at 5 per cent or less.

STRENGTH AND INK TESTS OF PAPER

The hardness and the finish of the paper were determined by the combined judgment of several experienced papermakers, as we know of no method of reducing these qualities to a numerical standard. From comparison of sheets, which differed only by the silicate content and the alum requisite for its precipitation, the statement is warranted that the use of silicate in every case produced a harder and a smoother sheet. The Mullen tests of the papers in this series when averaged show a gain of 12 per cent in favor of the papers containing silicate. Ink resistance was studied in four different grades of paper by the floating method with standard ink. In three of these grades the papers containing silicate showed better ink resistance than those which contained none. This may be attributed to the increased retention of rosin in the paper, there being no reason to believe that sodium silicate can of itself increase the resistance of paper to water or to an aqueous ink.

In studying the effect of the addition of silicate to the beater, it was observed that the increment of ash increased over a period of several hours, sometimes reaching its maximum as late as 7 hours after stock containing silicate came on the machine. This is interpreted to mean that a larger precipitation of the silicate and better retention develops as the white waters from which the silicate has been precipitated are returned to the machine and to the beaters.

EFFECTS ON COLORS

Silicate, like rosin size, should be handled in such a way that its alkalinity does not affect adversely the colors used in the paper. Where the silicate is added first and is completely precipitated with alum before the addition of the color, no interference with the color has ever been experienced, but it is not safe to add the necessary quantity of alum and then a color sensitive to alkali before the silicate, because when the silicate is added it is certain to be for a short time locally in excess, and the full strength of some coloring materials is not restored by the alum. Owing to better retention some papers show an improvement in color when silicate is used and when handled with proper regard to its alkaline character, satisfactory coloring is always practicable in papers containing silicate.

From the point of view of maximum retention, the experiments point to the following order of additions to the beater as the most satisfactory: (1) Silicate, (2) alum for the silicate, (3) rosin size, (4) clay or other fillers, and (5) alum for the rosin size. Many variations are possible without destroying the effect of the silicate, this being simply the preferred practice.

PAPERS TREATED WITH SILICATE

The grades of paper which have been considered in careful tests include cover, envelope, papeterie, book, writing, kraft, tissue and boxboard. It would not be reasonable to say that silicate of soda should be used in every mill or even in every mill that requires the properties in paper which the use of silicate tends to impart, but it has been found possible in some cases

to make a paper of acceptable quality with a less expensive furnish and in other cases to get a grade of hardness and finish not otherwise obtainable. In mills where the trim from combining machines using silicate as an adhesive is furnished to the beaters the resulting paper may be improved by precipitating the silicate with alum. Silicate of soda is always helpful in bristol boards, because of the cementing action on the fibers which tend to stand up as a fuzz or beard on the surface. This characteristic is also very useful in certain kinds of wrapping paper and the cheaper grades of writing paper. All paper that is judged by its rattle and snap can be improved by the judicious use of silicate.

SILICATE-STARCH GOOD SIZING AGENT

As pointed out by Wrede,³ papers intended for printing may be sized with silicate of soda or with silicate and starch in such a way as to provide all the qualities required in printing and with the added advantage that they are not subject to discoloration on long exposure to light, as are all papers which have been sized with rosin size. Printing ink is an oily substance and it is possible to produce a paper which gives perfect satisfaction in offset printing without showing much resistance to water. The more general recognition of a distinction between water resistance and oil resistance will do much to extend the usefulness of silicate of soda in the paper industry.

Belgian Industry Statistics

The table given below shows the production of the various branches of Belgian industry during 1920. These statistics were estimated at the Ministry of Economic Affairs and were obtained from production figures and average prices:

Industry	Production Metric Tons	Value Francs
Mines:		
Coal.....	22,413,535	2,016,000,000
Coke.....	1,801,280	180,000,000
Briquets.....	2,923,363	321,500,000
Quarries:		
Marble, building stone, flux, paving stone, sand.....		231,000,000
Cement.....	648,147	95,600,000
Metallurgy:		
Pig iron.....	1,128,518	564,259,000
Zinc.....	82,960	149,000,000
Copper.....	4,850	25,000,000
Finished steel.....	1,071,856	810,000,000
Finished iron.....	197,032	170,000,000
Mechanical construction figures unobtainable.		
Glass:		
Plate glass.....	*2,419,315	109,000,000
Window glass.....	*26,449,583	300,000,000
Flint-glass industry.....		96,000,000
Chemistry:		
Soda, potash, chloride of lime, calcium chloride, etc.....		38,152,000
Sulphuric acid, hydrochloric acid, nitric acid, sodium sulphate, superphosphates.....		183,925,000
Soap.....		18,000,000
Matches.....		11,500,000
Byproducts of coal—		
Alkali.....	894	57,182,000
Anhydrous ammonia.....	62	
Ammoniac sulphate.....	9,048	
Benzene.....	4,194	
Dissolvent.....	759	
"Brai" (rosin, pitch, tar).....	25,872	
Naphthalene.....	4,702	
Creosote.....	5,543	
Tar.....	28,304	10,000,000
Light oils.....	1,785	
Powder and explosives.....	2,200

Radium Production in America—I

Grinding—Dissolving—Filtering—Crystallization—Conversion of Chloride Into Bromide—Tubing of Radium Bromide—Recovery of Vanadium and Uranium—Recovery of Radium From the Gelatinous Silica Press Cake

By H. D. d'AGUIAR

THE American radium-bearing ores are the carnotites found chiefly in the Paradox Valley of Colorado, deposited on and impregnating a fine grained, porous sandstone.

The carnotite, which is potassium uranium vanadate, is a bright canary-yellow crystal when pure, but the ore, as found, has usually the appearance of a dirty, mud-colored sandstone. The ores usually run from 1.5 to 2.8 per cent uranium oxide, though occasionally pockets containing ores running 10 and even 18 per cent uranium oxide are found. The higher grade ores are readily distinguished from the low-grade ones by their color, which becomes more and more yellowish as the values increase.

As radium is a product of the disintegration of uranium and as the amount of radium present is always in fixed proportion to the amount of uranium present, the percentage of uranium is an index of the milligrams of radium contained.

The ore occurs in pockets and though the actual mining difficulties may be few, the location of the deposits far from railroads, in a country where even wagon roads are next to impossible, together with the shortage of water, makes the mining operation difficult enough. The ore as mined is sacked and transported by burros to the camp, where it is weighed and assayed for uranium content by means of the alpha ray electroscope. The bags are then marked with lot numbers and shipped to the reduction works.

GRINDING AND DISSOLVING

On arrival at the reduction works the various lots of ore are weighed and stored separately in a dry warehouse. The action of water on the ore alters the uranium:radium ratio and would carry away much of the fine high-grade material; therefore it is important to keep the ore dry.

From the warehouse the ore is sent to the grinding mills, where it is reduced by means of Hardinge or other suitable ball mills to pass 60 mesh. The lots are either run through the mills separately or lots of about the same values are combined into one large lot.

Two samples of the ground ore are taken. One is sent to the analytical laboratory for determination of uranium oxide, vanadium oxide, barium and calcium oxides and moisture. The other sample is sent to the electroscopic laboratory, where the percentage of uranium present is determined by radio-activity with the alpha ray electroscope. The results obtained by the two laboratories on uranium should check closely.

The analyzed ore is sent to the dissolving tanks. These tanks are acid-proof and good service is given by tanks constructed of acid-proof brick. The tanks are shallow and about 60 sq.ft. in area. The ore is spread in a layer from 4 to 6 in. deep on the bottom of the tanks

and is then wet down carefully with water or weak vanadium-uranium liquor from previous extractions. So prepared, the ore is ready for the extraction of the uranium, vanadium and radium. This is accomplished by treating the ore with the amount of hydrochloric acid necessary to dissolve all values as computed from the chemical analysis and the number of pounds of ore placed in the tank. During the addition of the hydrochloric acid the ore is continually turned and agitated so that the acid may act evenly on the entire mass. Sulphuric acid is then added in sufficient quantity to precipitate all barium and calcium. Water or more weak vanadium liquor from previous extractions is then added. The stirring is continued throughout the entire operation. The liquor, which now contains the uranium and vanadium in solution and the barium-radium sulphate in suspension, is removed by decantation through an opening in the side of the tank at a height flush with the top of the bed of sand tails. The bed of sand remaining in the tank is washed with water or more weak

FLOW SHEET OF RADIUM PRODUCTION PLANT

vanadium liquor and is again stirred to remove any sulphates. The liquor first decanted and the first wash waters go to a storage tank, while the succeeding wash waters, being weaker in radium values, go to a second storage tank. These weak liquors are used for first washes on new lots of ore, the sulphates accumulating in this tank being periodically cleaned up and combined with other lots of sulphates.

The sand tails before being conveyed to the dump are carefully sampled and a sample is sent to the electroscopic laboratory for analysis. The tails should show little or no activity. An activity equivalent to 0.05 per cent uranium oxide should be the maximum permissible, the determination being made immediately after drying and cooling.¹

FILTERING

The liquor and sulphates in the first storage tank are siphoned or pumped to a wooden frame filter press equipped with Duriron pumps. The vanadium-uranium liquor passing through as filtrate is pumped to storage tanks. The first wash waters from this operation are also pumped to this tank, while the remaining part of the wash water which shows vanadium is pumped to the storage tanks containing the last washes from the sand tails.

When the press cake has been washed, the press is stripped and the cake sampled and weighed. One portion of the sample is sent to the analytical laboratory for determination of moisture and barium sulphate. The other portion goes to the electroscopic laboratory, where the radium content is determined by means of the emanation electroscope.

These crude sulphates are transferred to pressure kettles, where water and a calculated excess of sodium carbonate are added and the mass is "cooked" under steam pressure until the barium sulphate together with the radium sulphate, which always follows barium, is converted to the carbonate with formation of an equivalent amount of sodium sulphate.

The contents of the pressure kettles are then pumped through iron frame filter presses. The sodium sulphate liquor, containing the excess unchanged sodium carbonate, is run to the sewer. However, a careful check is kept on this liquor by sampling frequently and having the samples analyzed to make sure that it contains no radium. A very minute activity is sometimes found, but as a rule these liquors contain no radium at all.

The frames and cloths used on the filter presses are carefully inspected to make sure that they fit perfectly and that the cloths are free from thin spots or holes. Any leakage would be the cause of losing radium-bearing material of considerable activity. The radium-barium carbonate so obtained is stripped from the presses, sampled and weighed. One-half of the sample is sent to the analytical laboratory for the determination of barium and moisture, while the other half goes to the electroscopic laboratory for determination of radium content by the emanation method.

The barium-radium carbonate so obtained is dissolved in a tank with dilute, sulphate-free hydrochloric acid. This acid chloride solution, together with the insoluble matter, is pumped through a wooden frame filter press. The filtrate, together with the first wash waters, is run to a storage tank, while the later, weaker, wash

water is run to a second storage tank. The press cake, which is chiefly gelatinous silica, requires thorough washing to remove all possible soluble values. This cake is never washed free from radium values, so when the activity has been reduced to the minimum compatible with economical working of the plant, the cake is stripped, and when a sufficient quantity has accumulated the whole lot is reworked separately.

The chloride liquor in the first tank is treated with sulphuric acid to precipitate the barium-radium chloride present as the sulphate. Samples of the liquor are tested from time to time during the precipitation to insure an excess of sulphuric acid.

TREATING THE WASH WATERS

At this time an excess of sulphuric acid is added to the second tank containing the wash waters. The small amounts of sulphates so precipitated are allowed to settle to the bottom of the tank. The bulk of the supernatant liquor is then decanted through a filter press having wooden frames. When the liquor has been drawn down close to the sulphates, they are stirred up and thus transferred to the press. The sulphates in the main tank are not allowed to settle, but pumping is commenced as soon as sulphation is completed. The filtrate and washings may be discarded. The sulphate cake when washed free from acid is stripped, sampled and weighed. Barium sulphate and moisture are determined in the analytical laboratory and the radium content in the electroscopic laboratory by the emanation method.²

These second sulphates are transferred to the pressure kettles, mixed with a calculated excess of sodium carbonate, and converted to carbonate by heating with steam under pressure in the same manner as before. When the conversion has been completed, steam is shut off and the carbonates and liquor are pumped through an iron frame filter press and washed with water until the washings are free from alkali. The washings are tested from time to time by the electroscopic laboratory to make certain that they are free from radium. When the wash water runs free from alkali, the carbonate cake is stripped, sampled and weighed. The radium content is determined by the electroscopic laboratory and the barium carbonate and moisture by the analytical laboratory.

If the foregoing operations have been properly conducted, the second carbonates will be of sufficient purity, of high activity, and suitable for delivery to the crystallizing laboratory.

CRYSTALLIZATION

The crystallization laboratory receives from the plant the weighed, analyzed carbonates. The laboratory is charged with the number of milligrams of radium contained in each lot of carbonates delivered. The efficiency of the extraction work is reckoned from the number of milligrams of radium in the ore treated divided into the number of milligrams in the carbonates delivered to the crystallization laboratory. The percentage so obtained will be raised somewhat by the radium recovered by reworking the press cake from the first carbonates.

The carbonates received from the plant are dissolved

¹The process of extracting the values by means of nitric acid has been tried. Though perhaps a gram or so of radium has been produced by this method of extracting, it is needlessly expensive and has never met with much favor.

²For the precipitation of the sulphates a solution of sodium sulphate can be used to good advantage instead of sulphuric acid, providing the price of the sodium sulphate is low enough to make the cost of the sulphate radical contained as low as or lower than the cost of the sulphate radical in the sulphuric acid.

in dilute, sulphate-free hydrochloric acid. The acid solution of barium-radium chloride so obtained is filter pressed through a wooden frame press. The filtrate from the press goes to a system of large crystallizing pots. These pots may be either of acid-proof enamel ware or earthen ware. The cake in the filter press, again consisting chiefly of gelatinous silica, is washed thoroughly with sulphate-free water, the washings going to a special pot for concentration before being combined with the main portion of the filtrate. The press cake is stripped, sampled and analyzed for moisture and radium content. After weighing, the amount of radium contained can be computed. This cake is then returned to the plant for reworking, and the crystallizing laboratory is credited with the amount returned.

The volume of the chloride liquor obtained in dissolving the carbonates and washing the press cake is measured. A sample is then taken and sent to the electroscopic laboratory for determination of the radium content. The milligrams so found plus those found in the press cake should equal in amount the milligrams in the carbonates delivered to the laboratory.

SEPARATION OF RADIUM FROM BARIUM

Separation of the radium from the barium by fractional crystallization is started as soon as the chloride liquor has been sampled. This first liquor is concentrated by boiling until close to the saturation point. It is then allowed to cool. On cooling, crystals of radium-barium chloride will form. These crystals will be richer in radium in proportion to barium than was the original liquor. The mother liquor is removed from the crystals and its volume carefully measured. It is then sampled and the radium content is determined by the electroscopic laboratory. The crystals are dissolved in sulphate-free water and hydrochloric acid. The volume of this solution is also measured, a sample taken, and the amount of radium contained determined. The solution of the first fraction crystals is again crystallized, when there will be obtained another crop of crystals richer in radium in proportion to barium than were the first crystals. The first mother liquor is concentrated further, cooled, and another crop of crystals obtained which are weaker in radium than the first fraction, but richer in radium in proportion to barium than was the mother liquor from which they were obtained. These processes are repeated until the mother liquors are practically free from radium.

It is never possible in practice to get the mother liquors free from all traces of radium. The fractional crystallizing continually reduces the bulk of the crystals, with a corresponding increase in the amount of radium per pound of barium. When the bulk of the crystals is small enough they are transferred from the pots to a table, where the crystallization is carried on in large silica dishes. The procedure on the table is exactly the same as in the pots, the only difference being that a smaller volume is handled. As the purity increases with each fractionation, more and more care is required in handling the succeeding fractions, as the loss of a little liquor or a small amount of crystals with their high radium content is a serious matter.

CONVERSION OF CHLORIDES INTO BROMIDES

When the fractionation has proceeded to a point of sufficient purity, the fractions are delivered to the bromide table, where the chlorides are converted to bromides and the purification by fractional crystallization

is continued. The bromide crystallizing is usually carried out in a separate room. Each fraction received from the chloride tables is carefully sampled and analyzed. The reason for duplicate determinations on these samples is to avoid even the temptation of theft as well as to supply an accurate record of the work in the two branches of the crystallizing laboratory.

The fractions as received by the bromide room, after sampling, are carefully carbonated with ammonium carbonate, which precipitates the radium and barium as carbonates. The carbonates are separated from the liquid by filtration through suction funnels. The carbonates on the filter are washed with dilute ammonium carbonate solution and then dissolved in hydrobromic acid. This original bromide solution is measured, sampled and analyzed as a check against losses in the conversion process. After sampling, the crystallization of the bromides is commenced. The crystals of each fraction and also the mother liquors of each fraction are sampled and analyzed. When the purity has been carried to a point where the crystals can be handled in small dishes of about 6-in. diameter, further fractionations are carried out in a water bath. The final fraction is carefully crystallized, the mother liquor is decanted from the crystals, and the crystals are carefully dried to remove all moisture. The radium bromide so obtained is immediately tubed.

TUBING OF RADIUM BROMIDE

The tubing process is the transferring of the radium bromide to a small thin-walled glass tube by means of a small metal applicator. The tube is then sealed by drawing to a point in a small gas flame. The process must obviously be conducted where there are no air currents to carry away any of the dry radium bromide. The tube is preferably made of potash glass and is of a size selected to hold easily the amount of radium bromide ready for tubing. While transferring the bromide to the tube it is held with forceps and not with the fingers. It is perhaps easier to hold the tube in the fingers while filling, but this is done only at the risk of severely burning the fingers. A radium burn is by all means to be avoided as, unlike a burn from fire, it continues to attack the flesh and if at all severe even parts of the finger bones will be destroyed.

The different fractions obtained in the bromide crystallizations are preferably tubed separately so that a check on the crystallizing work may be kept. With a little practice a good operator can keep the bulk of the radium in the first two fractions, the succeeding fractions containing only a small percentage of the total amount. Carelessness will result in the radium scattering through all the fractions, resulting in needless work and loss of time.

The tubed radium from the bromide room is delivered to the electroscopic laboratory for estimation by means of the gamma ray electroscope. Tubed radium, of course, on account of its activity is never kept in the electroscopic laboratory, but in a safe or vault provided for the purpose and located some distance from the laboratory, the radium being taken in only for estimation and immediately returned. A reading is made on the tube as soon after its delivery by the crystallizing laboratory as possible so that the crystallizing laboratory may know the amount tubed in each fraction and be guided in their work. The first reading, made immediately after tubing, is never accepted as anything but approximate. Four days later a second reading is

made and recorded and the final reading is made after thirty days have elapsed since tubing, the radium then being in equilibrium with its emanation and the results accurate and final. The final readings on each tube are credited to the crystallization laboratory. The amount tubed divided by the amount delivered to the crystallization laboratory will give the percentage of recovery.

RECOVERY OF VANADIUM AND URANIUM

The vanadium-uranium liquors in the storage tanks, from which the sulphates have been removed, are allowed to collect until the tanks are nearly full. Sodium carbonate is added until the liquid is but slightly acid, then sodium nitrite is added, and the tank is heated to boiling by steam. If the liquid is but slightly acid at this time, the vanadium oxide, carrying some iron and uranium and considerable amounts of soda salts, will be precipitated. The precipitation is never complete, but if the acidity is checked by volumetric control tests during the process, a very good recovery is obtained. The precipitate will be granular in character and will filter readily. When the reaction has been completed, the vanadium oxide is separated by filter pressing. The cake is analyzed for moisture and vanadium oxide. A comparison of the vanadium oxide so precipitated with the amount in the ore treated will give the percentage of recovery. The vanadium oxide so precipitated finds a ready-market with manufacturers of ferro-alloys.

If it is desired to recover the uranium oxide remaining in the filtrate from the precipitation of the vanadium oxide it is returned to tanks for the purpose and the uranium precipitated as sodium uranate by addition of sodium hydroxide until the liquor is alkaline. The sodium uranate so precipitated will carry the rest of the iron in the solution and also the major portion of the unprecipitated vanadium. The precipitate is extremely hard to handle through a filter press and the lack of a market for any considerable amount of uranium salts makes it nearly always advisable to run the filtrate after precipitation of the vanadium to the sewer without attempting to recover the uranium. Such will be the case, at least, until there is a definite market for the impure sodium uranate.

RECOVERY OF RADIUM FROM THE GELATIOUS SILICA PRESS CAKES

The press cakes are dried and ground in a ball mill with one-half their weight of a mixture containing two-thirds lampblack and one-third barium chloride. The mixture is transferred to a graphite crucible and roasted at a temperature of about 1,050 deg. C. The result is the dehydration of the silica and conversion of any sulphates to sulphides. The mixture is permitted to cool and is then transferred to an acid-proof tank, where it is extracted with dilute, sulphate-free hydrochloric acid. When the reaction is complete, the chloride liquor is separated from the residue by filtering through a wooden frame filter press. The press cakes are discarded. The filtrate is run to a tank together with all the sulphate-free water used in washing the press cakes. Washing is continued until the filtrate is free from barium as determined by testing with dilute sulphuric acid. The chloride liquor is then treated with sulphuric acid to precipitate the radium-barium chlorides present as sulphates. The sulphates are separated from the acid solution by filtering through a wooden frame filter press and washing with water until the filtrate is free from acid. These sulphates are treated

exactly as were the sulphates from the dissolving tanks. They will be of a higher purity than the sulphates from the dissolving tanks and unless they are combined, after weighing and analysis, with a lot of sulphates obtained by direct extraction, the first carbonates from them can, as a rule, be delivered to the crystallization laboratory.

Part II will be published in a subsequent issue.

German Potash Industry

From statistics published by the Statistische Reichsamt (Federal Bureau of Statistics) it will be noted that the production of potash salts fell greatly during the war, but rose very rapidly from less than 8,000,000 tons in 1919 to over 11,000,000 tons in 1920. The latter figures approximate those for 1912 and 1913, as will be seen from the following, which gives statistics for gross production of potash salts from 1911 to 1920:

	Tons		Tons
1911.....	9,706,507	1916.....	8,642,887
1912.....	11,070,014	1917.....	8,938,738
1913.....	11,607,511	1918.....	*9,438,251
1914.....	8,171,512	1919.....	7,772,036
1915.....	6,879,476	1920.....	11,386,439

*Alsace production is included in first half of 1918, but not for the later periods.

The refining process through which potash salts are passed before they are sold reduces the weight considerably. The following table contains figures for sales of potash salts for the years 1911-1920, inclusive:

	Metric Tons		Metric Tons
1911.....	4,541,653	1916.....	3,775,961
1912.....	4,736,103	1917.....	4,598,857
1913.....	5,187,298	1918.....	4,834,327
1914.....	3,998,756	1919.....	4,155,104
1915.....	2,991,071	1920.....	4,313,325

It will be noted in the table following that in 1913 over 500,000 tons of potash was exported, whereas in 1919 there was exported less than 200,000 tons and in 1920 less than 250,000 tons. According to the explana-

FOREIGN AND DOMESTIC SALES OF POTASH, 1911-1920

1919.....	28,266	608,767	637,033	174,969	812,002
1920.....			690,000	233,644	923,644

tion furnished by the Statistische Reichsamt, one of the principal reasons for this great decrease in the export of potash is the fact that during the war great efforts were made to produce potash in North America so as to become independent of Germany. According to the figures furnished, nearly 250,000 tons was exported to North America in 1913 and only 70,000 tons in 1919.

Taxation of American Enterprises in Germany

The taxes payable by American enterprises in Germany and the conditions under which the taxation is imposed are enumerated in an article entitled "Taxation of American Corporations in Germany," prepared for the Bureau of Foreign and Domestic Commerce. Multigraph copies have been made and will be supplied by the bureau and its district and co-operative offices to interested inquirers who refer to file No. CL-C2.

Unusual Grain Growth Due to Critical Strain

By A. P. KNIGHT

THE fact that unusually large grains may develop during annealing metals which have undergone a certain amount of cold work is not new. Many investigators have caused the formation of very large grains in critically strained metal by annealing for long periods at temperatures very close to the melting

FIG. 1. ROUGH SURFACE OF SHELL AFTER TAPERING.

point of the metal in question. It is perhaps not so common for great grain growth to occur due to a critical strain previous to annealing where the cold-working of metal is rather severe and the annealing is done at as low a temperature as is practicable.

One of these problems recently taken up for investigation in this laboratory was an aluminum coffee pot, manufactured in this plant, the bottom of which had a very rough appearance, while the sides were smooth. These coffee pots are made by cold-drawing aluminum circles through dies into the form of shells. The shells are then annealed for forty-five minutes in a muffle maintained at 800 deg. F. This method of annealing, which has been used for some time on similar aluminum coffee pots of a smaller size, caused complete softening of the cold-worked metal

FIG. 2. VERTICAL SECTION OF SHELLS AFTER DRAWING AND AFTER TAPERING. $\frac{1}{2}$ ACTUAL SIZE

and produced a fine-grain structure. The shells are then put through a tapering operation which enlarges the diameter of the bottom and forms a tapered shell. Fig. 1, a photograph of the bottom of one of these larger coffee pots, shows this rough appearance. This rough surface did not appear until after the tapering operation, which caused more or less of a stretch in the metal forming the bottom. Fig. 2 shows the shell cut in half just before the tapering operation, placed inside a shell split after tapering. It will be noticed that the second operation reconverts the lower portions of the side walls into part of the bottom, thus shortening the length of the shell.

The bottom of the pot shown in Fig. 1 was etched with hydrofluoric acid in order to develop the grain structure, as it was suspected that the rough surface was due to deformation of very large grains previously caused by "overannealing." Fig. 3 is a photograph of this bottom after etching. As can be seen, the metal in the bottom of this aluminum coffee pot is composed of crystals which are unusually large. It will also be noted that the shape and size of the overgrown crystals in Fig. 3 correspond to the rough spots in Fig. 1, and the bottom of the shell after the first forming operation (Fig. 2). It is evident that the rough spots in Fig. 1 are individual grains of great size which are more clearly shown on etching. Some of these grains measured as much as $\frac{1}{2}$ in. in length.

FIG. 3. ETCHED SURFACE SHOWN IN FIG. 1. $\frac{1}{2}$ ACTUAL SIZE

Such observations led to the belief that the outer edge (about $\frac{3}{4}$ in. in width), composed of small grains, represented metal drawn down from the side and much more strongly worked than the original bottom, both before and after the anneal. It appeared also that the inner portion was metal which must have undergone a very moderate amount of work.

It was at first thought that these coffee pots had been annealed at too high a temperature. If this had been the case, the whole shell would have shown large grains, but it was found upon examination that the large grains were confined to the bottom of the tapered

shell. The walls or sides of the shell were found to be composed of uniformly small grains characteristic of properly annealed aluminum.

In order to settle the question as to whether the cause of the unusually large grains in this article was local overheating, one of the cylindrical shells before it had been annealed was taken and a strip $\frac{1}{2}$ in. wide extending across the bottom and part way up the side was cut out with a hacksaw. This strip was then annealed in a small laboratory electric muffle at a uniform temperature of 900 deg. F., for one hour. Under these conditions cold-worked aluminum should show a uniformly small grain structure.

Microphotographs were made from the annealed strip

FIG. 4. STRIP CUT FROM SHELL BEFORE ANNEALING OR TAPERING

4 per cent. A test-bar of aluminum elongated 4 per cent and annealed under the above conditions shows grains measuring $1\frac{1}{2}$ in. in length. As the amount of elongation was increased from 4 to 14 per cent in different test-bars, the grain size on annealing decreased to a point where they were barely visible to the unaided eye. In the test-bars which were elongated over 14 per cent, the crystals as shown by the photographs in their paper are too fine to be seen without the aid of a microscope.

With the view of finding out if lowering the temperature of annealing or shortening the time in the muffle would prevent this excessive grain growth, a strip of metal was cut from another aluminum shell and annealed at 700 deg. F. in the laboratory electric muffle for one hour. This strip was polished, etched and examined throughout its length under the microscope. It was found to be composed of uniformly fine grains and to be soft and ductile.

A large number of these cylindrical shells were then annealed in the regular factory muffle at 700 deg. F. and after they had been put through the tapering operation

FIGS. 5 TO 7. MICROSTRUCTURE OF AREAS A, B AND C (FIG. 4) RESPECTIVELY. $\times 35$

of metal at the Points A, B and C, the locations of which are shown in Fig. 4. Fig. 5, taken from the side of the shell quite near to the bottom (Position A), shows a fairly fine grain for aluminum. B and C are represented in Figs. 6 and 7, and show such great grain size that only part of any one crystal can be shown at the magnification used—in fact, these are the smallest crystals that could be found in the section.

The only conclusion that can be arrived at from the above microphotos taken from a small strip of metal which has had a uniform laboratory anneal is that part of this metal was in a "critically strained" condition before annealing. As is well known, metal which has been worked or strained a certain definite amount (usually within fairly narrow limits) will produce very large grains on proper annealing. This is especially true if the metal is annealed for a long time and at a temperature near its melting point. Carpenter and Elam, in a paper entitled "Crystal Growth and Recrystallization in Metals," read before the British Institute of Metals' on Sept. 15, 1920, show by a series of elongation tests on aluminum followed by annealing at 1,022 deg. F. for sixty-five hours that this critical point for aluminum corresponds to an elongation of

all were examined for rough appearance of the bottom which would denote excessive grain growth. Not one was found that had this rough surface. Apparently a difference of only 100 deg. F. in the annealing temperature prevented abnormal grain growth in the critically strained metal of the bottom of this aluminum coffee pot.

Since the above tests have been made several lots of these pots have been annealed at the lower temperature and the rough appearance of the bottom has been entirely eliminated, although the metal is formed in the same machines as before and possess the same original deformation.

Rome Manufacturing Co., Rome, N. Y.

Hydro-Electric Projects in Spain

Hydro-electric projects to develop a total of over 750,000 hp. are under consideration in Spain at the present time, according to a recent report of Commercial Attaché Cunningham, Madrid. Of these, the Douro enterprise is the most important and is expected to develop energy to the extent of 450,000 hp. With scarcely 10 per cent of the 6,000,000 hp. of hydro-electric resources in Spain being utilized at this time, further development is essential to the best interests of the country.

The Manufacture of Nitroglycerine

A Concise Account of the Technology Involved in the Commercial Production of Nitroglycerine and a Consideration of the Properties of This Commodity Which Are Responsible for Its Important Industrial Applications

BY E. M. SYMMES

Chemical Department, Hercules Powder Co.

WHILE there are many articles in the technical literature bearing on the manufacture of nitroglycerine, most of them refer to small-scale operations or describe processes so old that they cannot be compared with present practice. There have been as many advances in the science of glycerine nitration in the past few years as there have been in similar chemical manufacturing lines, but they have not received the attention here that they deserve and that they have been accorded abroad.

This short article will deal with the manufacture of nitroglycerine as applied to the manufacture of high explosives where large-scale operations are the rule and where chemical purity in the restricted sense is not necessary. This does not mean, however, that purity and stability are neglected, but that only such precautions are taken as to the purity of the product which are important in view of safety and the high quality of the finished material.

From a review of the literature on the subject it might be thought that charges of nitroglycerine of about 100 to 200 lb. each were made, whereas the present practice in modern plants is to nitrate approximately 1,300 lb. of glycerine, producing about 3,000 lb. of nitroglycerine at each operation. About 7,000 lb. of mixed nitric and sulphuric acids is required to accomplish this.

The chemical and physical properties of nitroglycerine have been stated so frequently that reference to them is merely to refresh recollection. Glycerine is a triatomic alcohol, and nitration proceeds according to the equation:

STRENGTH AND PURITY OF MATERIALS USED IN MAKING NITROGLYCERINE

While some small quantity of nitroglycerine would be made by using strong nitric acid according to the equation just stated, the yields would be very low on account of the water which is formed interfering with the course of the reaction. In commercial practice comparatively large quantities of sulphuric acid are added to the nitric acid before use, to combine with the water as fast as it is formed and thus remove this water from the sphere of action. Typical nitrating acids are as follows:

	Per Cent
H ₂ SO ₄	55.00-54.50
HNO ₃	42.50-44.25
HNOSO ₄	0.50- 1.25
H ₂ O.....	2.00- 0.00

After nitration, spent acids result. The composition of typical spent acids from the above mixed acids would be:

	Per Cent
H ₂ SO ₄	76.60-75.90
HNO ₃	6.40- 6.60
H ₂ O.....	17.00-17.30

The nitrosylsulphuric acid should be as low as it is possible to obtain, since it is inert in the nitrating reactions. The sediment, or mud, in the mixed acids should also be as low as possible because sediment contributes to lessened yields of nitroglycerine. Water-white acids are usually used; these are made by permitting the acid to stand in storage tanks until it is in that condition.

In general, the mixed acids should have as little water present as possible, even going so far in this respect as to have a negative quantity. This is accomplished by using only high-strength nitric acid and fuming sulphuric acid, the latter containing 20 to 40 per cent free SO₃. It can be realized that the less water present in mixed acid the less the volume of the spent acid produced, and consequently the less nitroglycerine lost by solution in the spent acid.

The glycerine employed is the so-called dynamite glycerine, an article of commerce which contains about 98.5 per cent glycerine. It has a slight odor, somewhat similar to acrolein, and undoubtedly contains either a slight amount of this body or something similar to it. No effort is made to deodorize it before use in nitroglycerine manufacture. Small quantities of fatty acids are particularly undesirable on account of producing a scum, or slime, later on during the separation of the nitroglycerine from the spent acids, or in washing the nitroglycerine with water to remove the acid it has dissolved. Its specific gravity at 15 deg. C. should be not less than 1.26175. The color of the glycerine is no criterion of its usefulness. A water-white glycerine may sometimes be entirely unsuitable, whereas a dark-colored sample may work perfectly.

Glycerine, when exposed to severe cold, crystallizes into transparent crystals which melt at 17 deg. C. Both crystallization and melting take place slowly.

USE OF GLYCERINE-SUGAR SOLUTION AND SIMILAR MIXTURES

Various patents have been taken out, both in this and in foreign countries, on the use of a glycerine-sugar solution to take the place of glycerine alone. Such a mixture can be nitrated, separated, washed and neutralized in the same way and with the same apparatus as is used with glycerine alone, since the sugar, on nitration, becomes a nitrosaccharose, which is perfectly soluble in the nitroglycerine. On account of the cheaper price of the sugar, an appreciable saving is introduced. A great many tons of cane sugar are consumed in the United States every year in this way by the explosives industry.

Many patents have also been taken out on the production of explosives containing nitroglycerine and other bodies which will lower the freezing point of the mixture to a considerable degree. Most of these are mixtures of nitroglycerine with a nitro-aromatic compound such as nitronaphthalene, nitrotoluene, nitroxyline, and the like, but some depend upon the nitration of a mixture of glycerine and diglycerine. This mixture can be prepared by heating glycerine in contact with a condensing agent, such as sodium carbonate or acetate.

FIG. 1. VIEW OF NITRATOR AND ELEVATED RESERVOIR FOR WEIGHING AND STORING GLYCERINE

Water is split off under such conditions and distilled from the glycerine, leaving a mixture of glycerine and diglycerine, the relative proportions of the two depending upon the time and temperature of heating. Such a mixture can be nitrated, separated, washed and neutralized in the same apparatus used for nitrating glycerine itself.

The appearance of such nitroglycerine substitutes differs little from nitroglycerine itself. The one having a certain substitution of sugar is a little more viscous, and that containing some diglycerine has a slightly darker color.

DESCRIPTION OF NITRATOR AND ITS OPERATION

The type of nitrator in use at the present time is shown in Fig. 1. It will be noted that the reservoir for the glycerine at the left is supported on a frame at such a height that the glycerine will flow by gravity through an iron pipe and spigot to the nitrator. The glycerine feed-tank and its support are on platform scales to permit measuring accurately the quantity used, since the proportion of the glycerine to the nitric acid must be carefully controlled. This glycerine has been previously heated to a temperature of about 100 deg. F. to render it more fluid. This heating is done in a separate house, so arranged that the drums in which the glycerine is received may be drained for 24 hours in a heated room, since glycerine clings very tenaciously to the walls of the container. About 1½ lb. of glycerine will remain clinging to the sides of the drum no matter how long this draining may continue. This amount could be recovered only by washing out the drums with water, an operation which would be uneconomical on plants not having a glycerine refinery.

The mixed acid is weighed out in a tank placed on scales outside the nitrating house and transferred to the nitrator by gravity or compressed air, depending

upon the topography of the ground. All of the mixed acid, amounting to about 7,000 lb., is put into the nitrator at once.

The nitrator is of steel-plate construction, having three concentric seamless steel coils in it. These coils carry cold calcium chloride brine to remove the heat of the reaction. Agitation is accomplished by two vertical shafts having paddles at their lower ends. The shafts are supported by a double bearing in the upper framework so that no step-bearing inside the nitrator is necessary. Naturally, such a step-bearing could not be lubricated and would be a source of great danger. The agitator is driven by a steam engine, which can be seen in Fig. 1. A steam-engine drive is subject to fewer interruptions than any other type and its speed can be closely regulated merely by a throttle and governor. Reliability of agitation is important, since, if agitation stops, the incoming glycerine will not be driven under the surface of the cold acid, but will tend to remain on or near the surface of the acid and will cause local heating which will soon lead to decomposition and finally ignition. To avoid the possibility of accident in case the motive power for agitation fails suddenly, a perforated air coil is placed in the bottom of the nitrator, so that the charge can be agitated temporarily in such case.

TEMPERATURES OF NITRATION

With refrigerating effects commonly employed, a charge of about 1,300 lb. of glycerine will be nitrated in from 50 to 60 minutes. The refrigerating machines in use at the present time are of the 40-ton compression type. To permit sufficient capacity of the brine coolers, about 20,000 gal. of calcium chloride brine is circulated

FIG. 2. LEAD TANK IN WHICH NITROGLYCERINE IS SEPARATED FROM THE SPENT ACIDS

from a storage tank through the refrigerating machine and through the coils of the nitrator. This whole amount of brine is brought to a temperature of a few degrees below 0 F. before starting operations in the morning, and will rise only a few degrees as each charge is run through the nitrator.

Temperatures of nitration range from 45 to 34 deg. F., the lower temperatures being used whenever possible. It is well known that the lower the temperature of nitration the higher the yield of nitroglycerine. The temperatures commonly employed are lower than the freezing point of nitroglycerine, yet no freezing takes

place either during nitration or during the subsequent separation, probably because of the influence of the relatively large amount of acid present. That the nitroglycerine does not freeze at these temperatures when undergoing separation and when it contains only a very small amount of acid is probably due to the super-cooling phenomenon to which nitroglycerine is subject.

At the end of the nitration a large stop-cock at the base of the nitrator is opened and the emulsion of nitro-

FIG. 3. RUBBER-LINED GUTTERS IN WHICH NITROGLYCERINE FLOWS TO STOREHOUSE

glycerine and spent acid flows down into an open, shallow, lead tank, known as the separator. (See Fig. 2.) Here it is allowed to stand until the nitroglycerine comes to the surface as a clear, pale yellow oil, very similar in appearance to a light lubricating oil, and the milky spent acid has settled to the bottom. The sides of the lead separator have thick plate-glass windows set in by glycerine litharge cement, so that the course of the operation can be watched. On looking through these windows the contents of the separator will first be seen as a homogeneous emulsion. In a few minutes small globules of nitroglycerine can be seen to move slowly upward and on reaching the top merge into a layer of nitroglycerine which spreads over the entire surface of the tank. This action continues until, on looking through the windows, a sharp line is seen between the two layers, when separation is considered complete.

PURIFICATION OF THE NITROGLYCERINE

The spent acid is then drawn off through a bottom stop-cock and sent to the acid recoveries for working up into nitric and sulphuric acids of usual strengths, to be used over again in the process. The nitroglycerine, still containing a small quantity of dissolved acids, is dropped slowly into a tank of warm water at about 90 to 100 deg. F., agitated with air, and, after settling for a few minutes, is sent to the next house by gravity flow through a V-shaped wooden gutter lined with sheet rubber. (See Fig. 3.) In this house, the so-called neutralizer, it is received in lead tanks holding a solution of sodium carbonate. These are shown in Fig. 4. Such a quantity of sodium carbonate is present as will be certain to show a small excess after all the acid has been neutralized. Agitation is here also accomplished with air. This washing with alkaline solution is continued until the nitroglycerine gives a neutral test to litmus paper. A few hours' settling after this process reduces the moisture which the nitroglycerine con-

tains to 0.30 to 1.50 per cent. The nitroglycerine is stored under a small quantity of the sodium carbonate solution, and drawn out through rubber hose as required for use.

METHODS OF HANDLING NITROGLYCERINE, AND ITS IMPORTANT USES

For transportation to the point of consumption, the dynamite or gelatine mixing houses, or the smokeless powder mixers, the nitroglycerine prepared as above is drawn out of the neutralizing tanks by a rubber hose into small buggies having copper-lined tanks and rubber-tired wheels. The valve controlling the flow of nitroglycerine to these buggies is nothing more than a gigantic laboratory pinch-cock, operating by mere compression of the rubber hose.

The platform scale used to weigh out the nitroglycerine required is covered with sheet rubber, as are also the weights, so that no shock would be possible even if the weights were accidentally dropped. Scrupulous cleanliness is enforced throughout these operations. Workmen are required to wear standard uniforms and nail-less shoes, so that there will be no possibility of shock or friction against metallic objects on the floor.

Important uses for nitroglycerine other than for dynamite are for oil-well torpedoes and double-base smokeless powder. For shooting oil wells a can containing nitroglycerine and provided with a detonating cap is dropped down the well, exploding when it reaches the bottom. Double-base smokeless powder consists of nitrocotton and nitroglycerine, the amounts of the latter sometimes reaching as high as 40 per cent. Such a smokeless powder has many advantages over one made of nitrocotton only, and is the standard military powder for Great Britain.

FIG. 4. NEUTRALIZERS IN WHICH FINAL PURIFICATION IS EFFECTED

PHYSIOLOGICAL PROPERTIES OF NITROGLYCERINE

Nitroglycerine exerts a temporary poisonous effect on human beings. The small quantities of it volatilized in the air of the working buildings will give a person unaccustomed to it a severe headache in the course of a few minutes. Mere contact with the skin also results promptly in headaches, on account of the rapid absorption into the system. Such headaches last for about 12 hours, and after this time no permanent ill effects are ever observed. Contact with nitroglycerine for two or three days causes the system to build up an immunity to its effects, and after this period none of the poisoning effects is noticed. Such immunity is very quickly lost, however. Absence from work for two days or more will destroy it, and the painful process of again acquiring it will have to be repeated.

Extensive medical investigations have shown that no permanent ill effects are suffered by workmen in a nitroglycerine plant. Every large explosives company has in its employ many old and experienced workmen who have been in contact with nitroglycerine every working day for many years. No ill effects which could in any way be attributed to nitroglycerine have ever been proved, in spite of thorough medical investigations undertaken with the idea in mind that such ill effects were present. This differs markedly from experience in the manufacture of many or all of the nitro-aromatic explosives, where severe, definite and permanent poisonous effects are experienced unless great precautions are taken to prevent entry of such compounds into the human system.

This article is intended to cover only a few points in connection with manufacture of nitroglycerine for ultimate use as dynamite or gelatine dynamite, blasting gelatine, smokeless powder or as a liquid for shooting oil and gas wells. These uses comprise practically the entire consumption of nitroglycerine with the exception of a relatively small quantity used as a 1 per cent solution of nitroglycerine in pure grain alcohol, which is employed in medicine as a heart stimulant. No chemical process is involved in the manufacture of dynamite and gelatine dynamite, assuming that the nitroglycerine has already been prepared, since a mere incorporation with suitable absorbents is all that is required. Blasting gelatine is simply a solution of soluble nitrocotton in nitroglycerine, the solution being aided by warming the mixture.

To show the importance of glycerine nitration in the United States it might be mentioned that 50 per cent of the entire production of glycerine in this country is converted into nitroglycerine for use both as liquid nitroglycerine and in commercial high explosives.

Wilmington, Del.

Argentine Cane-Sugar Production in 1920

The Argentine Director of Rural Economy and Statistics reports that the total area under cultivation of sugar during 1920 was 233,700 acres. The amount of cane milled was 3,099,722 metric tons, producing 209,553 metric tons of sugar. During the previous year a total of 297,640 tons was produced. Most of the sugar was produced in the Provinces of Tucuman, Jujuy, Santa Fe and Salta. Small-scale production took place in the Chaco, Corrientes and in the Territories of Formosa and Misiones. The annual consumption of Argentina averages 220,000 metric tons. During the six years 1915-1920 Argentina imported 305,913 tons and exported 137,534 metric tons of sugar.

A New Salt Cake and Hydrochloric Acid Furnace

BY N. A. LAURY

IN THIS journal in May, 1913, there appeared an article from *Zeitschrift für Angewandte Chemie* by Dr. Theodor Meyer in which he said: "The great problem of the muriatic acid industry—the mechanical furnace—is still a problem of the future, and for the present there is little hope that it will soon be solved." Two types of furnaces, both survivals of early days, are still the only ones in common use. Against the pot and muffle furnace there stands the objection of heavy and disagreeable hand labor, and against the mechanically agitated muffle, commonly represented by the Mannheim furnace, there are the poor quality of the salt cake, small capacity and rapid wear of moving parts.

The plant described herein, on which the writer has filed patent papers, was built last year by the Aetna Explosives Co. at Emporium, Pa., and is being successfully operated. It is an internally oil-fired rotary, requiring no hand labor except charging, and it produces 20 tons of good salt cake a day with a minimum of wear.

The most obvious difficulties expected either did not appear at all or were at length overcome. The absorption of the hydrochloric acid from the very dilute gas

FIG. 1. BALL MILL FURNACE

to form acid of commercial strengths was accomplished by ample cooling of the gas and recirculation of the absorbing acid. The design and specific proportions required for the provision of sufficient heat at one end to produce high-grade salt cake, without causing fusion of the charge in any part of the furnace or wasting too much heat at the outlet, were based on data obtained in small-scale experiments. Owing to the internal application of the heat, the charge does not cake on the walls objectionably. A protective crust 2 in. thick forms over the brick lining, so the bricks are never exposed and thus last indefinitely.

THE FURNACE

Fig. 1 shows a longitudinal elevation of the furnace. It consists of a combustion chamber with oil-burning equipment and a horizontal two-chambered revolving cylinder.

The combustion chamber is lined with firebrick and mounted on a truck for convenience in moving to reach the interior of the furnace. It is made of $\frac{1}{2}$ -in. steel shell 10 ft. long and 4 ft. 8 in. in diameter. The combustion chamber nozzle, which projects slightly into the furnace, is a plain iron casting lined with firebrick. The oil burner is the low-pressure type. It is supplied with air by a Sturtevant blower and with oil by Goulds pumps. The air and oil connections are flexible to

permit the fore and aft movement of the combustion chamber. There is a course of SiloCel brick between the shell and the firebrick lining. This fully protects the shell and saves heat, as at full operation the hand can be borne on the shell.

The furnace is a steel shell in two sections of different diameters, united in the middle by cast-steel flanges. The front or hot section has a 9-in. firebrick lining. Its diameter inside this lining is $4\frac{1}{2}$ ft. and its length 10 ft. It has a plain unlined cast-iron head with a central port 2 in. greater in diameter than the combustion chamber nozzle, to permit discharge of the salt cake. The latter is also beveled toward the bottom to give more room for the discharge. A casing is loosely fitted around this end of the furnace through which the salt cake drops to a worm conveyor. A fan is connected to the top of this casing to conduct the smoke from the hot salt cake to the stack. At the junction of the two sections of the furnace and dividing them into separate chambers there is a cast-iron plate which is bolted to the cast-steel flanges. This plate has a 2-ft. hole in the center for the gas and radial slots near the periphery through which the salt cake passes from the grinding chamber to the hot chamber.

The grinding chamber is lined with chilled iron plates. It is 12 ft. long and $4\frac{1}{2}$ ft. in diameter. It has a cast-iron head which also has a chilled iron lining. It is insulated with asbestos covering. The grinding is done by 3-in. diameter cast-iron balls. An 18-in. cast-iron flue conducts the gas from the grinding chamber to the dust chamber. The charging of the salt and niter cake is also done through this flue.

The large gear on the furnace is driven by a pinion and chain and a 50-hp. motor. After the first few revolutions at starting a little less than 25 hp. is all that is required. The furnace rotates at 20 r.p.m.

THE ABSORBING SYSTEM

The gas is freed from dust, filtered free of sulphuric mist, cooled and absorbed in water.

The dust chamber is made of red brick with an inner

FIG. 2. GAS FILTER

course of acid brick. It is 10 ft. square, 15 ft. high and the walls are 16 in. thick. There are clean-out doors at the bottom.

A 12-in. chemical stoneware line about 50 ft. long conducts the gas to the filter. This is a wooden tank

with tarred staves and acid-brick lining. (See Fig. 2.) It is 6 ft. in diameter and 20 ft. long. The filtering medium is a bed of rice-sized coke 24 in. deep.

The coolers consist of four rows of 6-in. silica ware S pipe over which water is run.

The gas goes to the towers (Fig. 3) through two 8-in. lines; one to each row of six towers run in parallel. From the tower outlets 8-in. connections join at the Duriron fan inlet. The towers are $2\frac{1}{2}$ ft. in diameter and 15 ft. high and are made of chemical stoneware and packed with ordinary ring packing resting on brick grills. In each row of six the gas travels up the first three through a common header, down the next two and up the last. The water is run into the last tower of each row and the HCl solution is circulated at the rate of about 30 lb. a minute on each tower by a pulsometer.

FIG. 3. ABSORBING SYSTEM

The air, separated in the pulsometer splash boxes on the tops of the towers, goes through a 3-in. chemical stoneware line to a coke-packed vessel over the last towers, where it is scrubbed free of HCl by the incoming fresh water for the towers.

The acid is stored in two rubber-lined wooden tanks 12 ft. diameter and 8 ft. deep.

A cheap and very good cement for the stoneware joints is made by stirring into melted coal-tar pitch a small amount of ground barytes, silica or china clay and some short-fibered asbestos. The proportions are chosen for the different joints so that the cement does not get too hard on the cold ones or too soft on the hot ones. A ring of asbestos rope is first placed in the joint and the cement then worked in like putty before it cools.

OPERATION

The normal rate of running is 1 ton of salt cake an hour. This requires 9 to 10 gal. of fuel oil. The burner is easily regulated so that a sootless gas enters the furnace. The heat is regulated according to the quality of the cake. Prime cake has to come out of the furnace at somewhat above 1,000 deg. F. The niter cake is coarsely ground in a single roll coal crusher weighed in a buggy, the required weight of salt shoveled on top of it and the charge slowly dumped into the elevator. This is done every 4 or 5 minutes according to the size of charge handled. It is thoroughly ground in the grinding chamber of the furnace and also has given off 25 per cent of its HCl when it reaches the hot chamber. The balls are always free and clean and the walls of the grinding chamber never get coated.

To keep the crust of cake on the brick lining of the hot chamber at the right thickness a loose rail 9 ft. long is kept in it. If two or three heavy rails are used, the crust is all cut away, but if only a light one or none at all is used the crust gets too thick. The

outside of the furnace is always cool enough to bear the hand.

If there is any interruption of the feed, the fire must be shut off or the charge will fuse on the middle plate and close up the ports. The combustion chamber then must be pushed back and the ports opened with long bars. The operators soon learn to avoid this troublesome job.

The gas leaves the furnace at 300 deg. F., which is close to the minimum that prevents condensation in the grinding chamber, iron flue and dust chamber and represents the best fuel economy possible in the apparatus. Condensation starts in the flue to the filter. The temperature at the filter inlet is 160 deg. F. and at its outlet 125 deg. F. and the coolers bring it down to 80-90 deg. F.

The acid circulated on the strong towers is kept at 20 deg. Bé. unless stronger acid is required. At this strength its temperature does not go above 85 deg. F. even in warm weather. The temperature and strength gradually decrease in each succeeding tower until in the last tower the acid is 3 deg. Bé. and not much warmer than the entering water.

The volume of the cool gas runs close to 2,000 cu.ft. a minute and at the fan it contains 0.006 g. per liter of unabsorbed HCl. At the inlet to the tower the gas contains about 0.05 g. per liter, so that somewhat over 1 per cent of it is lost.

The constant volume and composition of the gas greatly simplifies the filtering, cooling, absorption and the control of the strength of the product. Unlike the intermittent processes, the latter takes care of itself if the water is admitted uniformly.

POINTS TO BE CONSIDERED IN OPERATION OF ABSORPTION SYSTEM

Acid of 20 deg. Bé. has been made with gas containing even less than 3 per cent HCl by volume. This is explained by the cooling effect of the pulsometers, the circulation of 350 to 400 lb. of acid a minute and particularly by the distribution of the absorption over a number of towers in which each step in the process is carried on separately.

Guide posts in rational absorption are indicated by the partial pressures of aqueous hydrochloric acid of different strengths:

Deg. Bé.	Mm. Hg.	Deg. F.
22	174	86
20	33.3	86
19.95	31.5	86
19.2	15.5	86
13.36	0.57	86
3	0.00117	77

At 3 deg. Bé., the strength of the acid in the final tower, the partial pressure is so low and the solubility of HCl is so great that even a very dilute gas is absorbed. This is illustrated by the fact that the small amount of 3 deg. Bé. acid drawn into the fan is rapidly concentrated to 13.36 deg. Bé. by the exit gas containing only 0.0006 g. per liter, unless it is continuously drained out. Below 13.36 deg. Bé. the conditions for absorptions are most favorable. The specific heat of the solution drops but little relatively, while the heat of solution of the HCl has not yet reached its maximum. Furthermore, 13.36 deg. Bé. is the most stable concentration, as it can be distilled without change of strength at 227.37 deg. F.

From 13.36 deg. Bé. to the standard strength of 20 deg. Bé. the process should be regarded as one of con-

centration. The stronger and cooler the gas the better, and the solution should be circulated in large volume. At 19 to 20 deg. Bé. there is a sharp rise in the partial pressure. This is the standard strength and seems to be the maximum for stability. At 22 deg. Bé. the partial pressure is so high that there is considerable loss of HCl on exposure and it should not be used except where this loss is overbalanced by a special demand.

There should be a good in-pull at the joint between the furnace and the flue to the dust chamber. At the top of the dust chamber the draught is normally minus $\frac{1}{8}$ in. of water, at the filter inlet minus $\frac{3}{8}$ in., at the cooler inlet $1\frac{7}{8}$ in., at the inlet to the towers minus $2\frac{3}{8}$ in. and at the fan inlet minus 5 in. The fan is driven at a speed of 1,500 r.p.m. by a 5-hp. motor.

The plant requires a charge man, a tower man and a furnace operator for 24 hours. A repair man and helper are usually kept busy in the daytime.

QUALITY OF PRODUCTS

All commercial strengths of acid can be made. It is clear and has the usual light yellow color. It compares in analysis with pot and muffle acid as follows:

	Deg. Bé.	H ₂ SO ₄ Per Cent	Fe Per Cent	As ₂ O ₃ Per Cent	Free C.
Rotary.....	20	0.07	0.02	0.00013	Trace
Pot and muffle.....	20	0.09	0.02	0.00003	Trace

It was proved by absorbing gas from the furnace through distilled water in glass apparatus that the iron in the product comes from the action of the acid on the material of the towers and packing.

The salt cake is of good color and compares in analysis with pot and muffle cake as follows:

	H ₂ SO ₄	NaCl	Fe ₂ O ₃	Al ₂ O ₃	Insol.	CaSO ₄
Rotary.....	1.21	1.68	0.31	0.21	0.32	0.54
Pot and muffle.....	1.40	0.90	0.20	0.10	0.33	1.32

The size of the cake particles in the cold stockpile is shown by the screen test:

	NaCl, Per Cent	H ₂ SO ₄ , Per Cent
Whole sample.....	1.33	1.04
On 10 mesh, 10.6 per cent.....	1.65	1.10
On 30 mesh, 30.9 per cent.....	1.38	2.78
On 40 mesh, 6.2 per cent.....	1.47	0.63
On 50 mesh, 5.4 per cent.....	1.42	0.29
On 60 mesh, 2.9 per cent.....	1.42	0.29
Through 60 mesh, 42.8 per cent.....	1.24	0.28

The high salt in the 30-mesh portion indicates that these are the largest lumps that come out of the furnace. The 10-mesh fraction probably lumps up on cooling outside.

Rockville Center, L. I.

Export of Copra and Coconut Oil From Philippines

Nearly 10,000,000 kilos of copra cake, copra and coconut oil was exported from the Philippine Islands from Aug. 13 to Aug. 25 last, according to a report of the Philippine Bureau of Customs. The shipments were valued at several million pesos.

The huge consignment, which is believed to be the biggest exported in many months, went to American and European markets. Approximately 1,811,000 kilos of copra cake was exported to Hamburg, Germany, while 1,222,000 kilos went to London, England, and over 1,100,000 kilos to American markets.

The copra shipments were distributed as follows: 1,060,000 kilos went to Germany, 318,000 kilos to Holland and 304,000 kilos to America.

Coconut oil went mostly to the United States, to the amount of 1,222,000 kilos. Holland received 670,000 kilos and London 670,000 kilos.

A Bibliography and Abstracts of Chromium Steels

Chronological Arrangement of Some of the Principal Papers on Chromium and Chromium Alloy Steels Published During the Period 1798 to 1919, With Brief Summary of Their Scope

BY F. P. ZIMMERLI

THIS bibliography on chromium, or chromium alloy steels, is arranged in chronological order. An effort has been made to abstract papers dealing directly with chromium steels and such parts of other papers found to deal with chromium steels. In case the original article was not read it is so stated and both the abstract read and the original journal are listed. In no case, however, are abstracted articles used if the original could be obtained.

FROM 1798 TO 1877

(1) Memoirs on a new metallic substance contained in red lead of Siberia and which one proposes to call "chrome" on account of the property it possesses of coloring the combinations which it enters. L. N. Vauquelin. *Ann. Chim.*, 1798, vol. 25, pp. 21-31 and 194-204.

(2) Concerning the alloys of chromium with iron and with steel. M. P. Berthier. *Ann. Chim. Phys.*, 1821, vol. 17 (second series), pp. 55-64. By fusion in a crucible using forced draft coke fire steel containing 1 to 1.5 per cent chromium was obtained. A knife and a razor made from them had a beautiful damascened finish.

(3) On the alloys of steel. J. Stodart and M. Faraday. *Phil. Trans.*, Roy. Soc. of London, part 1, 1822, pp. 253-270. The authors prepared two alloys of steel and chromium on a laboratory scale. The chromium added should have resulted in approximately 1 and 3 per cent. They were malleable and gave a fine damask.

(4) Note on the crystallization and alloys of chromium. M. E. Fremy. *Compt. rend.*, 1857, vol. 44, pp. 632-634. He reduced chromate and oxide of iron by charcoal, into an alloy with a needle-like structure, very hard, scratching quartz and hardened steel.

(5) Alloys of iron and chromium. M. Sergius Kern. *J. Iron and Steel Inst.*, 1875, vol. 2, pp. 654. A note to the effect that a 74Cr:25Fe alloy was glass hard and that 97.5Fe:2.5Cr was found malleable.

(6) On chromium pig iron made by the Tasmanian Iron Co. E. Riley. *J. Iron and Steel Inst.*, No. 1, 1877, pp. 104-108. It contains 6 to 7 per cent Cr, has a high melting point and is difficult to puddle. Oxide of chromium makes a thick cinder. Welding experiments showed that Cr has none of the deoxidizing powers of Mn.

FROM 1878 TO 1886

(7) Note on chrome steel. G. Rolland. Abstracted in *Proc.*, Inst. of Civil Engineers, vol. 53, 1878, p. 384, from *Ann. des Mines*, vol. 13, p. 152. Chromium increases the hardness and strength but it cannot replace carbon. Analyses show from 0.08 to 9 per cent Cr. Carbon as high as 1.10 per cent. At this time

the steel was made only at Brooklyn (U. S.), Sheffield, (England) and Unieux (France) by crucible or Siemens' furnace.

(8) Magnetization of iron. John Hopkinson. *Phil. Trans.*, Roy. Soc. of London, vol. 176, 1885, part 2, pp. 455-469. Magnetic tests, specific resistance and chemical analysis of 35 chromium steels (forged, annealed and oil-hardened). No marked effect of Cr indicated.

(9) Note on the production, constitution and properties of chrome steel. M. Boussingault. *J. Iron and Steel Inst.*, 1886, vol. 2, pp. 807-830. Shows that Cr does not give iron a tempering power as carbon does, contrary to the assertions of Julius Bauer. Brief description of the difficulties involved in manufacture.

(10) On chrome, pig iron and steel. M. Brustlein. *J. Iron and Steel Inst.*, 1886, vol. 2, p. 770. Describes fracture and a few physical properties of chromium alloys produced at the Unieux works (France).

FROM 1887 TO 1892

(11) The status of chrome steels. H. M. Howe. Abstracted in *J. Iron and Steel Inst.*, 1887, vol. 2, p. 345, from *Eng. and Min. J.*, vol. 14, p. 242. Suggests the following definition: Chromium steel is a variety of steel the physical properties of which are influenced more by chromium than by other non-ferrous elements it contains. This shuts out so-called chromium steels containing but traces of chromium, or none at all.

(12) Note on chrome steel projectiles. *J. Iron and Steel Inst.*, 1887, No. 1, p. 458.

(13) Chrome steel. B. F. Hart and J. Calish. Abstracted in *J. Iron and Steel Inst.*, 1889, No. 1, p. 376, from *Iron*, vol. 33, p. 78. Manufacturing methods at Brooklyn. Tests employed on material used in St. Louis bridge.

(14) On critical points of iron and steel. F. Osmond. *J. Iron and Steel Inst.*, 1890, No. 1, pp. 38-80. Determines that presence of Cr considerably raises A_r . Influence of the maximum temperature before cooling on A_r is greater in Cr than in C steels. A brief bibliography is appended.

(15) Alloys of iron and chromium. R. A. Hadfield, including a report by F. Osmond. *J. Iron and Steel Inst.*, 1892, No. 2, pp. 49-175. Early history and a description of the element Cr and methods of preparing it. The physical properties of ferrochromium and of chromium alloys with, and very low in, carbon. Chromium cannot replace carbon as a hardener, merely acting as an intensifier. In an appendix methods of preparing pure chromium are given. F. Osmond concludes that Cr interferes with and impedes the crystallization of iron. Location of critical points and their change with rates of cooling are reported. Chromium exists in elemental solution, in a compound of Cr, Fe and C in isolated particles, and the same compound

in solid solution. The melting points of some ferros are given.

(16) Chrome steel: its manufacture and uses with complete chemical analyses. F. Hart, Jr., and J. Calish. *Stevens Indicator*, vol. 9, 1892, pp. 49-65. A general article in which the authors give a list of the uses of various chromium steels; describe the more important chromium ores, the method of producing the alloys—especially that employed by the Brooklyn (N. Y.) Chrome Steel Works—their properties and methods for their chemical analyses.

FROM 1893 TO 1894

(17) Preparation of chromium and manganese at a high temperature. H. Moissan. *Compt. rend.*, vol. 116, 1893, pp. 349-351. Chromium oxide mixed with carbon is reduced with a current of 50 v. and 350 amp. Carbon analyzes up to 13 per cent, but if it is broken up, placed in a crucible, brasqued and covered with chromic oxide, Cr quite free from carbon results. By using mixed ores perfectly homogeneous Fe:Cr alloys are obtained.

(18) Some alloys of iron with molybdenum, tungsten and chromium as solutions. J. A. De Benneville. *J. Am. Chem. Soc.*, 1894, vol. 16, pp. 735-757. Alloys, with the exception of some amalgams, are solids at ordinary temperatures; as a solution, they exist only at high temperatures where the laws of solutions apply. From studies of acid attack he finds: (1) A chemical union between constituents. (2) These compounds are distributed uniformly through the alloys. (3) The more stable alloys are definite chemical compounds. (4) The less stable may be definite compounds such as cryohydrates.

(19) The physical influence of elements on iron. J. O. Arnold. *J. Iron and Steel Inst.*, 1894, No. 1, pp. 107-155. Carbide formed by high chromium is noted and the location of critical points given.

(20) Cementation steel, ferrochromium, ferrotungsten and chromium steel. H. Behrens and A. R. Van Linge. Abstracted by *J. Am. Chem. Soc.*, vol. 66, part 2, 1894, p. 452, from *Rec. Trav. Chim.*, vol. 13, pp. 155-188. Ferrochromium contained crystals (hardness in a ground mass of hardness 4.2). The latter is a much better heat conductor. Acids leave bayonet-shaped crystals, non-magnetic, hardness 7.5, analysis approaching $\text{Cr}_2\text{Fe}_3\text{C}_3$. Softer portions of the alloy contain considerable Cr and the hardness is closely connected with the quantity of carbon present.

(21) Chromium. H. Moissan. *Compt. rend.*, vol. 119, 1894, pp. 185-191. Heating chromium with large excess of carbon in electric furnace gives Cr_3C_2 in brilliant lamellæ with a greasy luster. Insoluble in concentrated or dilute nitric acid, aqua regia or concentrated HCl. Fused KNO_3 attacks it readily. Sp.gr. 5.62; harder than topaz, softer than carborundum. Another carbide, CCr , is obtained in lustrous needles sometimes 20 mm. long; sp.gr. 6.75; harder than glass or quartz.

FROM 1895 TO 1902

(22) Ternary alloys of iron with chromium, molybdenum and tungsten. J. De Benneville. *J. Iron and Steel Inst.*, 1895, vol. 1, pp. 202-253. By use of different solvents the author detects $\text{Fe}_3\text{Cr}_6\text{C}_4$ and $\text{Fe}_3(\text{CrMo})_3\text{C}_4$ and carbides of iron other than Fe_3C . An excellent physicochemical investigation.

(23) Chromium:iron alloys. L. Schneider. *J. Iron and Steel Inst.*, 1896, vol. 1, p. 398. Abstracted from

Oesterreichische Z. Berg und Hüttenwesen, vol. 33, p. 297. Rich Fe:Cr alloys which are occasionally used to manufacture exceptionally hard steels exhibit crystals in blow-holes and on the surface, increasing with the chromium.

(24) Welding chrome steel. R. Brown. *J. Iron and Steel Inst.*, 1896, No. 1, p. 472. Successful welding can be done with light blows gradually increasing in strength.

(25) The magnetic properties of iron. Dewar and Fleming. Abstracted by *J. Iron and Steel Inst.*, 1896, No. 2, p. 397, from *Proc.*, Roy. Soc., vol. 60, pp. 57-71. Chromium steels were studied at low temperatures.

(26) A new silicide of chromium. Ch. Zettel. *Compt. rend.*, 1898, vol. 126, pp. 833-834. A compound, SiCr_3 , is reported to be very stable and insoluble except in HF.

(27) Researches upon the combinations of silicon and chromium in ferrous products. A. Carnot and Guital. *Compt. rend.*, 1898, vol. 126, pp. 1240-1245. $3(\text{Cr}_3\text{C}_2)(\text{Fe}_3\text{C})$ exists in ferrochromium; $(\text{Cr}_3\text{C}_2)_3(\text{Fe}_3\text{C})$ in low-chromium steel.

(28) Magnetic properties of hardened steels. Mrs. Sklodowska Curie. Société d'Encouragement pour l'Industrie Nationale, 1898, pp. 37-76. Deals with magnetic properties of forty-eight hardened steel magnets in the form of rings and 20-cm. bars.

(29) Researches on the electrical conductivity and magnetic properties of upward of one hundred different alloys of iron. W. F. Barrett, W. Brown and R. A. Hadfield. *Proc.*, Inst. of Electrical Eng., vol. 31, 1900, pp. 674-729. Gives the list of specimens tested; study of their electric conductivity and magnetic properties.

(30) On the increase of electrical resistivity caused by alloying iron with various elements and the specific heat of those elements. W. F. Barrett. *Proc.*, Roy. Soc. of London, vol. 69, 1902, pp. 480-485. Among others three chromium-bearing irons were examined ranging from 2 to 9.5 per cent Cr plus slight impurities.

(31) Magnetic properties of iron. A. Abt. Abstracted by *J. Iron and Steel Inst.*, 1902, No. 2, p. 537, from *Ann. der Physik.*, vol. 6, pp. 774-783. Abt measured the permanent magnetic moment in a large number of hardened steels in different fields. Ni:Cr steel shows the greatest moment, then follow steels containing Cr, Ni, W, C and Mn.

(32) Concerning the magnetic properties of iron and steel at low temperatures. C. C. Trowbridge. *Electrical World and Eng.*, 1902. Abstracted by *Stahl und Eisen*, 1903, vol. 23, No. 1, pp. 150-151. Influence of low temperature depends on the chemical constitution and temporary physical condition, thermal and mechanical treatment of the sample.

FROM 1903 TO 1904

(33) Determination of the points of allotropic changes of iron and its alloys by the measurements of the variations in the electrical resistance. O. Boudouard. *J. Iron and Steel Inst.*, 1903, No. 1, pp. 299-377. Thermal analysis of chromium steels indicates the existence of an anomaly at the same temperatures on heating and cooling.

(34) Properties and constitution of chrome steels. Leon Guillet. *Compt. rend.*, No. 139, 1904, pp. 426-428. Heat-treatment of nineteen different alloy steels gave results somewhat similar to straight carbon steels except in case of double carbide steels.

(35) The development and use of high-speed steel. J. M. Gledhill. *J. Iron and Steel Inst.*, No. 2, 1904, pp. 127-166. Discusses high-tungsten and low-chromium steels.

(36) Chrome steels, L. Guillet. *Revue de Métallurgie*, 1904, pp. 155-184. Carbons from 0.043 to 0.464 per cent; Cr from 0.703 to 31.74 per cent discussed. Hardened pearlitic chromium steels act like carbon steels during quenching. Martensitic Cr steels soften somewhat on quenching, due to a tendency to form gamma iron, the less the lower the carbon. Annealing also softens. Double carbide Cr steels are softened by a quench from 850 deg. without undergoing any microscopic change. At 1,200 deg. C. the carbides dissolve in part or totally according to speed of cooling and initial content. Annealing destroys the double carbide in part.

(37) Heat-treatment experiments with chrome:vanadium steel. H. R. Sankey and J. R. Smith. *Inst. Mechanical Engineers*, parts 3 and 4, 1904, pp. 1235-1317. Open-hearth furnace steel containing C 0.297, Si 0.059, Mn 0.394, Cr 1.066 and V 0.169 was used. Differently heat-treated material was tested for tensile strength, reduction of area, elastic limit, elongation, Arnold's alternating stress, impact test, hard bending and twisting tests. Photomicrographs and cooling curves accompany the data. Comparisons with straight carbon and nickel steels are numerous.

FROM 1905 TO 1906

(38) Chromium steel. A. Brustlein. *Revue de Métallurgie*, 1905, pp. 508-515. Early manufacture at the Unieux Works (France). Production of 55 per cent ferrochromium in old crucibles was stopped when a cupola furnace at the St. Chamond Works started producing it. Steels were manufactured from 0.5 to 3 per cent Cr.

(39) Experimental evidence relating to the effect on mechanical and other properties of iron and its alloys produced by liquid air temperatures. R. A. Hadfield, *J. Iron and Steel Inst.*, No. 1, 1905, vol. 67, pp. 147-206. (Bibliography, pp. 206-220.) Results for all the common steels of Cr and Cr plus other alloying elements in chromium steels containing W, Ni, Mn, Cu and Mn:Si. No distinct effects of chromium were observed.

(40) The types of structure and critical ranges on heating and cooling of high-speed steels under varying thermal treatment. H. C. H. Carpenter. *J. Iron and Steel Inst.*, No. 1, 1905, pp. 433-473. Does not concern chromium steels as such. Photomicrographs show change in constituents by cooling from increasingly higher temperatures. At 1,100 to 1,200 deg. C. structure tended toward austenite, eventually becoming so. Tempering starts at over 500 deg. C.

(41) Recent research made upon industrial alloys and their importance. L. Guillet. *Revue de Métallurgie*, 1906, pp. 87-111. (Chrome steel, pp. 94-96.) General comments on quaternary steels, some of which contain Cr.

(42) Nickel:chrome steels. L. Guillet. *Revue de Métallurgie*, 1906, pp. 332-354. Twenty-eight Ni:Cr steels investigated. They may be pearlitic, martensitic and carbide, of gamma iron or of gamma iron with carbides depending on the sum of C:Ni and Cr; 1.65 per cent C is equivalent to 29 per cent Ni or 18 per cent Cr. Addition of increasing amounts of Cr to a nickel steel will put it through all intermediate

stages to even gamma iron and carbides. Mechanical properties of normal Cr:Ni steels can be reduced from their microstructure by comparison with nickel or chromium steels.

(43) Quaternary steels. L. Guillet. *J. Iron and Steel Inst.*, 1906, No. 2, pp. 1-142. The influence of Cr is superimposed to that of Mn in Cr:Mn steels; when Cr is sufficiently high a carbide is formed. Physical properties and microstructure depend on the sum of Cr, Mn and C being analogous to Cr:Ni steels.

(44) Chromium steel. Abstracted by *J. Iron and Steel Inst.*, 1906, No. 4, p. 926, from *Iron and Coal Trades Rev.*, vol. 73, p. 1263. Low-carbon ferrochromium is best for steel manufacture due to more even solution of carbide. Crystals of carbide cause flaws.

(45) On the art of cutting metals. F. W. Taylor. *Trans., Am. Soc. Mech. Engineers*, vol. 28, 1906. Chromium is shown to be an essential element in modern high-speed steel.

DURING 1907

(46) The influence of chromium on the solubility of iron for carbon and the formation of graphite. Goerend and Stadeler. *Métallurgie*, 1907, pp. 18-24. A_r is constant and equal to 710 deg. C. up to 21 per cent Cr; between 21 and 29 per cent Cr no such point was found. The freezing point varied from 1,130 deg. C. for 0 per cent Cr to 1,535 deg. C. for 62 per cent Cr. A small increase in Cr stops the formation of graphite by silicon. The greater the per cent of Cr the greater the per cent of C can be before the eutectic is reached. High Cr favors formation of gamma iron.

(47) The iron:chromium solutions. Treveschke and G. Tammans. *Z. anorg. Chem.*, 1907, vol. 55, pp. 402-411. Equilibrium diagram. By rapid cooling the Fe:Cr system is a pseudo-ternary one, consisting of Fe, Cr and a compound Fe_xCr_y . The structure and properties of chromium steels depend not only on the Cr content but also upon the temperature to which they have been heated in the liquid state.

(48) The melting of Cr:Ni:Fe alloys. H. Wedding. *Stahl und Eisen*, 1907, vol. 27, pp. 1590-1591. Mobility, the formation of blow-holes and piping gases evolved, on Ni:Cr:Fe alloys.

(49) Chromium:tungsten steels. L. Guillet. *Revue de Métallurgie*, 1907, pp. 5-25. Normal steels show pearlite, martensite or carbide of Fe, Cr and W, which is found with martensite, sorbite or troostite. Ordinary structure is that of a rapidly cooled industrial steel. Physical properties depend on the class: (a) Pearlite steels have tensile strength and elastic limit higher, elongation and resistance to shock lower than ordinary steels; (b) martensite steels have very high tensile strength and elastic limit, with low values for both shock resistance and elongation; (c) carbide steels have low shock values—other properties are dependent on the constituent which accompanies the carbide. Hardening or quenching changes pearlitic to martensitic steels. Martensitic and carbide steels may be softened by quenching (due to gamma iron) more than straight carbon steels. Time and temperature cause solution of carbides and hence intermediate values. Heating to 1,200 deg. C. and cooling sufficiently rapidly gives an extremely fine martensitic structure with high-speed steels. Even pearlitic steels are not in use, since they cost more than Ni:Cr, which they but slightly excel. Use will, in general, be limited to high-speed tools.

(50) Concerning a new chrome tool steel. L.

Guillet. *Revue de Métallurgie*, 1907, pp. 1025-1026. A steel whose analysis shows C 2.18 per cent, Cr 14.88 per cent, Mn 0.71 per cent, Si 0.19 per cent, and P and S traces was accidentally made by adding Cr twice in a ladle. As received it consisted of pearlite and double carbide. It cannot be rolled, and is forged with difficulty. Heat to 950, cool to 850 deg. C. and oil-quench, or heat to 1,050, and cool to 950 deg. C. and oil-quench, when it becomes useful for a cutting tool for steel or iron. It does not warp during quenching.

(51) The densities and specific heats of some alloys of iron. W. Brown. *Sc. Trans., Roy. Dublin Soc.*, vol. 9, ser. 2, 1907, pp. 59-84. Chromium up to 3 per cent added to iron increases specific volume about 0.00034 c.c. for 1 per cent of added Cr. Further addition to 9.5 per cent has no effect. Chromium has very little effect on specific heat when C is relatively high.

(52) Alloy steels for motor car construction. J. A. Mathews, *J. Franklin Inst.*, 1907, vol. 167, pp. 279-397. General résumé of the author's experience.

FROM 1908 TO 1909

(53) The determination of the hardness of the constituents of iron and steel. H. C. Boynton. *Stahl und Eisen*, 1908, vol. 28, No. 1, p. 740. Hardness of pearlite varies but little with the addition of Cr, W or Mn up to 1 per cent. More than this raised the hardness.

(54) Concerning the magnetic properties of a pure iron tested by Dr. Kruesler. E. Gumlich. *Stahl und Eisen*, vol. 28, No. 2, 1908, p. 1430. Removal of gases is difficult. Effects of heating to 1,400 deg. C. on molecular structure noted.

(55) Function of chromium and tungsten in high-speed steels. C. A. Edwards. *J. Iron and Steel Inst.*, 1908, No. 2, pp. 104-132. Case-hardening the nose of a high-speed tool increases cutting speed from 13 to 14.5 per cent. Steels containing more than 3 per cent Cr and 6 per cent W show a critical range beginning at 380 deg. C. In a high-speed tool chromium forms a double carbide with W which imparts high hardness and increases the resistance to tempering.

(56) The special steels in theory and practice. Walter Giesen. *The Iron and Steel Inst., Carnegie Scholarship Memoirs*, vol. 1, 1909, pp. 1-55. Nickel: chromium steels examined for hardness, impact strength, metallography and ability to be case-hardened. Normal Ni:Cr steels may have the following structure: (a) Pearlite and ferrite, (b) pearlite and carbide, (c) martensite and carbide, (d) martensite and gamma iron, (e) martensite and ferrite, (f) gamma iron and carbide, (g) gamma iron. Formation of martensite depends on sum of C, Cr and Ni; the ratio of equivalence of these elements being C 1.68 per cent, Cr 18.5 per cent, Ni 28.7 per cent. Increasing Cr forms carbide. Cr:Ni steels with pearlitic or gamma iron structure can be recommended for industrial or practical use. Chromium steels containing 0 to 8 per cent Cr and 0.5 per cent C, or 0 to 5 per cent Cr and 0.95 per cent C have pearlitic microstructure and differ very slightly from carbon steels. Hardness increases with Cr independently of carbon content; brittleness is less than in plain steels with same carbon. Chromium steels containing 8 to 18 per cent Cr and 0.3 per cent C, or 5 to 12 per cent Cr and 0.95 per cent C are of martensitic or troostitic structure, have high tensile strength and elastic limit, low ductility, high hardness and medium brittleness. Chromium over 25 per cent

with 0.3 per cent C or over 22 per cent with 0.95 per cent C produce very brittle alloys.

(57) Contribution to the study of steels for gears. L. M. Révillon. *Iron and Steel Inst., Carnegie Scholarship Memoirs*, vol. 1, 1909, pp. 161-217. Steels considered are divided into (1) steels containing neither Ni nor Cr; (2) Ni:Cr steels, hardened in oil or water; (3) Ni:Cr steels with high carbon capable of air-hardening; (4) high Ni steels with or without Cr. All steels were heat-treated, and tensile strength, elastic limit, elongation, reduction of area, shock strength and hardness determined. Higher Cr with a well-adjusted Ni content yields the best results with a simple treatment.

(58) Contribution to the study of special ternary steels. A. M. Portevin. *Iron and Steel Inst., Carnegie Scholarship Memoirs*, vol. 1, 1909, pp. 230-362. In steels containing 0.2 per cent C (a) the resistance to shear increases with Cr, but remains below 50 kg.; (b) steels of 7 to 13 per cent Cr have a high resistance, but low contraction on shearing; (c) in steels having more than 13 per cent Cr the resistance to shearing remains within 30 to 35 kg., but contraction increases and elastic limit under shear decreases. In steels containing 0.8 per cent C (a) and with 5 per cent Cr have high resistance and elastic limit in shear, but contraction is low; (b) steels having 7 to 14 per cent Cr have uniform resistance to shear; (c) steels containing over 18 per cent Cr show a decrease in resistance and elastic limit in shear, while contraction increases.

(59) Special steels. Léon Guillet. Abstracted by *Iron Age*, vol. 84, 1909, pp. 916-917, from report read at Fifth Congress of the International Association of Testing Materials at Copenhagen, Denmark, Sept. 7-11, 1909. Tendency of alloying is to raise mechanical strength, simplify thermal treatment and create special anti-friction steels. Analysis, mechanical properties and heat-treatment of one Ni:Cr:V and one Ni:Cr steel are given. Several Cr and Cr:Ni steels can be air-quenched. Anti-friction steels contain Cr 0.42 to 0.54, Ni 2.43 to 2.6 and C 0.33 to 0.62.

DURING 1910

(60) Thermal treatment of special steels. Léon Guillet. *Revue de Métallurgie*, 1910, pp. 489-495. General discussion dividing steels into (1) pearlitic, (2) martensitic, (3) "polyhedrique"—i.e., steels having high percentage of alloy element in solution in gamma iron; (4) carbide steels having a single or double carbide, not necessarily in solution.

(61) Chrome steel permanent magnets. W. Brown. *Sc. Proc., Roy. Dublin Soc.*, new series, vol. 12, 1909-10, pp. 349-353. Results on seven steels giving chemical composition and magnetic moment per gram when glass hard and annealed. Annealing has little effect on magnetic moment; 1.95 per cent Cr, 0.86 per cent C gives the best magnet. Discusses previous investigations.

(62) Some physical properties of 2 per cent chromium steels. H. McWilliams and E. J. Barnes. *J. Iron and Steel Inst.*, 1910, No. 1, pp. 246-267. The forged material was normalized, annealed, quenched in water and drawn at 400 deg. C., 550 deg. C. and 700 deg. C. respectively and tested. Carbon varied from 0.2 per cent to 0.85 per cent in six different steps. A thermal and microscopic analysis is presented.

(63) The A_2 point in chromium steel. Harold Moore. *J. Iron and Steel Inst.*, 1910 No. 2, pp. 268-275.

Critical ranges determined by Carpenter and Keeling's method. Magnetic change point curves also plotted. Ac_1 is progressively raised by Cr. Identity of the lower critical point with magnetic changes proves it to be $Ac_{2,3}$. Occurrence of Ac_2 below Ac_1 means that Fe_3C is insoluble in beta iron.

(64) Concerning two nickel:chrome steels. M. A. Portevin. *Revue de Métallurgie*, 1910, pp. 808-810.

Chemical Analysis	C	Si	S	P	Mn	Ni	Cr	Microhms per c.c.
Steel A.....	0.19	0.18	0.02	0.01	0.44	2.53	0.63	26.2
Steel B.....	0.19	0.17	0.02	0.01	0.53	2.69	0.64	32.2

The slight difference in composition cannot cause such a difference in resistance. In other steels a difference of 3.52 per cent Ni caused similar results. Photomicrographs show very dissimilar structure in A and B, due to the effect of previous thermal treatment both in liquid and in solid state.

(65) Report on the wear of steels and their resistance to crushing. Felix Robin. *Iron and Steel Inst., Carnegie Scholarship Memoirs*, 1910, vol. 2, pp. 1-265. (Cr steels 41, 152, 166.) Double carbide in Cr steels increases wear resistance, especially where the carbide is in numerous grains surrounded by fine martensite, as in annealed steels containing 2 per cent Cr. Cr:W steel is strongest against crushing among Cr, Cr:Ni and Cr:W steels. The straight Cr steel has the greatest interstrain hardness.

DURING 1911 AND 1912

(66) The chemical and mechanical relations of iron, chromium and carbon. J. O. Arnold and A. A. Read. *J. Iron and Steel Inst.*, 1911, No. 1, vol. 83, pp. 249-260, and discussion, pp. 260-268. Brief résumé of several previous investigations; analysis, manufacture and physical properties are listed.

(67) Case-hardening chromium steels. F. Giolitti and F. Carnevali. Abstracted by *J. Iron and Steel Inst.*, 1912, No. 284, p. 595, from *Atti della Reale Accademia delle Scienze di Torino*, vol. 46, pp. 409-432. A 2.3 per cent Cr steel was carbonized using CO, ethylene, and CO and charcoal, giving similar results to carbon steels. Cr causes an increase in the maximum carbon concentration of the carbonized zone.

(68) Contribution to the study of iron:chromium alloys, with special reference to their solubility in acid. Phillip Monnartz. *Metallurgie*, 1912, pp. 161-176 and 193-201. A treatise on solubility.

(69) Relations between the macrostructure and the crystallization of steel. M. N. T. Belarew. *Revue de Métallurgie*, 1912, 647-680. The kind of steel is quite incidental to the relation of crystalline structure to macrostructure.

(70) Various acoustic properties of steel as a function of their temperatures. Felix Robin. *Revue de Métallurgie*, 1912, pp. 413-470. Chromium and Si act more energetically than Mn and Ni in retaining vibrations. In alloy steels the duration of sound is in general raised by Cr.

(71) The corrosion of Ni, Cr and Ni:Cr steels. J. N. Friend, J. L. Bently and W. West. *J. Iron and Steel Inst.*, 1912, No. 1, pp. 249-258. Corroding media, tap water, sea water, hot water and dilute H_2SO_4 may be divided into two groups—acid and neutral. Acceleration tests with H_2SO_4 are misleading. There is an optimum concentration of Cr for resistance to attack. In neutral media corrosion resistance rises with Cr.

(72) Magnetic properties of special steels. O. Boudouard. Abstracted by *J. Iron and Steel Inst.*, 1912, No. 1, vol. 85, p. 575, from (a) *Compt. rend.*, vol. 153, pp. 1475-1478, (b) *Revue de Métallurgie Memoirs*, vol. 9, pp. 294-303. In carbon steels the electric resistance increases with carbon, while in the Cr steels irregularities appear to have no relation to carbon.

(73) The magnetic properties of a variety of special steels at low temperature. J. G. Gray and A. D. Ross. *Trans., Faraday Soc.*, vol. 8, 1912, pp. 115-134. Studies of two steels containing 1 and 4 per cent Cr respectively.

(74) Chromium:vanadium steel tires. Abstracted by *J. Iron and Steel Inst.*, part 1, 1913, p. 665, from *Iron Trade Rev.*, 1912, vol. 51, pp. 1217-1218. Tables showing physical properties and chemical composition of heat-treated Cr:V steels. After 121,000 miles a locomotive still had its Cr:V tires in good condition, while carbon steel tires require turning after 60,000 miles.

(75) Concerning chromium steels. M. Portevin. *Compt. rend.*, No. 153, 1911, pp. 64-66. Reports on hardness and microscopy of two high-chromium steels heated to 1,300 deg. C. and cooled in the furnace.

DURING 1913 AND 1914

(76) On the transformation points and the structure of nickel:chrome steels. Léon Guillet. *Compt. rend.*, No. 156, 1913, pp. 1774-1776. Tabulates sixteen Ni:Cr steels, the best of fifty samples. Shows transformation points on heating and cooling, chemical composition and structure. The addition of Cr to a Ni steel caused effects depending on the percentage of Ni and C.

(77) Differences between the structure and the composition of certain steels. M. Bres. *Revue de Métallurgie*, 1913, pp. 797-808. Report on four Ni:Cr steels having almost identical compositions, but different microstructure and mechanical properties. Different structures were caused by different casting practice and could not be removed by heat-treatment or work, but behaved as steels of their kind after hardening and tempering. These structures correspond perfectly with the corresponding mechanical properties. Control of the factors influencing such special structures would permit making different steels of the same composition.

(78) The magnetism of permanent magnets. Silvanus F. Thompson. *J. Inst. Electrical Eng.*, vol. 50, 1913, p. 217. Includes a bibliography of magnetism which covers many chromium steels.

(79) The corrodibility of nickel, chromium and nickel:chromium steels. J. N. Friend, W. West and J. L. Bently. *J. Iron and Steel Inst.*, No. 1, 1913, vol. 92, pp. 388-398. Nickel steels appear to resist corrosion very well for some time and then fail rapidly. A 20 per cent Cr steel is very resistant to acid corrosion.

(80) New researches upon the transformation points and the structure of nickel:chrome steels. Léon Guillet. *Compt. rend.*, vol. 158, 1914, pp. 412-414. Presents tables for 2 and 4 per cent nickel steels with different percentages of C and Cr, giving transformation points, structure, chemical analysis, hardness and resilience.

(81) High-speed steels. M. Denis. *Revue de Métallurgie*, vol. 11, 1914, pp. 4-94. A study of the cutting properties and their practical utilization.

(82) Studies upon the general properties of high-speed steels. M. Denis. *Revue de Métallurgie*, No. 6, 1914, pp. 569-669. General test methods for high-speed steels and the best treatment which can be applied.

(83) Permanent magnetism of certain chrome and

tungsten steels. M. B. Moir. *Phil. Mag.*, sixth series, vol. 28, 1914, pp. 738-748. Steel containing 8 per cent Cr showed a 5.5 per cent loss, against 2.8 per cent loss for 16 per cent Cr steel, but the former had a higher residual magnetism, so that it remained a stronger magnet.

(84) The magnetic properties of a graded series of chrome steels at ordinary and low temperatures. M. B. Moir. *Phil. Mag.*, vol. 27, 1914, pp. 830-842. Six chromium steels containing Cr 1 to 20 per cent were tested at 15 deg. C. and -190 deg. C. in forged and rolled condition after annealing and after quenching from 900 deg. C. Lowering the temperature diminished the susceptibility for low and increased it for high fields. The magnetizing field at which curves corresponding to 15 deg. C. and -190 deg. C. respectively crossed increased with Cr content up to 12 per cent in annealed specimens and then decreased.

(85) Magnetic habits of alloy steels. J. A. Mathews. *Proc.*, Am. Soc. Testing Materials, vol. 14, 1914, part 2, pp. 50-66. Dwells on chromium steel only as it is the universal magnet steel. Magnetic hardness might be measured by the ratio of residual density and coercive force. Relation of Brinell hardness to magnetic hardness is given.

(86) Chromium:vanadium steel wheels. Abstracted by *J. Iron and Steel Inst.*, 1914, No. 1, p. 372, from *Iron and Coal Trade Review*, 1914, vol. 89, p. 544. Particulars are given of results of different types of tender wheels on the Grand Trunk Railway.

(87) Cr:V rolled steel wheels. Abstracted by *J. Iron and Steel Inst.*, 1914, No. 2, p. 711, from *Iron Age*, vol. 92, p. 1106. In the drop tests, 896,000 ft.-lb. imposed before cracking or breaking; fractured tough and stringy fracture; steel uniformly hard. Analysis Cr 1 per cent, V 0.16 to 0.20 per cent and C 0.55 to 0.65 per cent.

(88) Mayari steel, its properties and uses. The Pennsylvania Steel Co. *Iron Age*, vol. 89, 1914, pp. 69-72. The steel is made with C up to 1.5 per cent. S and P are below 0.04 per cent and Mn is as desired. Nickel averages 1.25 per cent, while chromium runs 0.2 to 0.4 in one grade and 0.4 to 0.7 in the other. It is manufactured in the same manner as a straight carbon steel. It is difficult to weld. Commercial grades and uses are given, also some curves showing effect of heat-treatment.

DURING 1915 AND 1916

(89) The corrosion of high Cr steels, Robert Hadfield. Abstracted by *Iron Age*, vol. 97, 1916, pp. 202-203, from *Faraday Soc.*, 1915D. Compares various steels to high-chromium and stainless steel. Mechanical properties of stainless steel are given. High Cr steels are usually more resistant than most alloy steels and much more so than straight carbon steels.

(90) The thermo-electric properties of special steels. E. L. Dupuy and A. M. Portevin. *J. Iron and Steel Inst.*, 1915, vol. 91, pp. 306-336. Chromium has less influence than nickel.

(91) The effect of chromium and tungsten upon the hardening and tempering of high-speed tool steel. C. A. Edwards and H. Kikkawa. *J. Iron and Steel Inst.*, 1915, No. 2, vol. 92, pp. 6-31. Determines Brinell hardness after various temperings, using a constant rate of cooling. Chromium and carbon cause the greatest hardness, and lower the temperature at which hardening occurs.

Curves of specific gravity vs. tempering temperature and Brinell hardness vs. tempering temperature are similar and show great hardness for highest volume.

(92) Concerning the allotropic transformation and the microstructure of nickel:chrome steel. A. M. Masloff. *Revue de la Soc. Russe de Métal*, vol. 1, pp. 494 and 515, 1915. Abstracted in *Revue de Métallurgie*. Extracts, 1918, pp. 37-44. Chromium retards decomposition of austenite. A low Ni steel with enough Cr can be air-hardened. Cr increases homogeneity and hardness.

(93) Note on the relations between cutting efficiencies of tool steels and their Brinell or scleroscope hardness. J. O. Arnold. *J. Iron and Steel Inst.*, 1916, No. 1, pp. 102-104. Brinell or scleroscope hardness are useless for estimating the thermal stabilities of hardenites, the main cause of lathe efficiency.

(94) Initial temperatures and critical cooling velocities of a chromium steel. C. A. Edwards, J. M. Greenwood and H. Kikkawa. *J. Iron and Steel Inst.*, 1916, pp. 114-140. Steel contained 6.15 per cent Cr, 0.63 per cent C, 0.7 per cent Mn. Chromium imparts the property of self-hardening which in turn is governed by the rate of cooling.

(95) The transformation of special steels at high temperature. R. Honda, K. Tawara and H. Takagi. *J. Iron and Steel Inst.*, 1916, No. 1, pp. 1 and 244-254. Heating, cooling and magnetization curves are taken for the six alloy steels below, and results tabulated.

Steel	C	Si	Mn	P	S	Cr	W	V	Mo
1 D.S.W. steel.....	1.16	2.89	0.4	0.047	0.038	2.74			
2 Ultra capitol.....	0.66	0.08	0.08	0.018	0.016	3.43	16.81		
3 New capitol.....	0.64	0.05	0.01	0.015	0.012	3.73	14.63	0.011	
4 Bohler.....	0.82	0.18	0.26	0.003	0.016	3.71	14.63	0.20	0.17
5 Super-rapid Novo steel	0.59	0.22	0.06	0.028	0.23	2.86	18.81		
6 Becker diamond.....	1.05	0.16	0.35	0.009	0.012		3.17		

In the cooling curves the critical point remains almost constant but A_3 coincides with A_2 . Cooled from 1,000 deg. C. or higher, the A_3 transformation is displaced partly or wholly to a lower temperature (400 deg. C.).

(96) Manufacture and uses of alloy steels. H. D. Hibbard. *Bull.* 100, Bureau of Mines, pub. 1916, 72 pages. Brief notes on heat, manufacture, use, methods of treatment and physical properties. Steel containing Cr, Cr:Ni, Cr:V and high-speed steels are discussed.

(97) The critical points of self-hardening steels and of the formation of troostite and martensite. M. P. Dejean. *Revue de Métallurgie*, 1917, pp. 641-676 (chromium steels, pp. 661-666). Among self-hardening steels are the following: Cr, Ni:Cr, Cr:W, Ni:Cr:Cu. A series of cooling curves are obtained by varying the initial temperature and rate.

DURING 1917

(98) Some observations relative to the transformation points of special steels. Leon Guillet. *Revue de Métallurgie*, 1917, pp. 676-683. Analysis, transformation points, structure and physical properties of two series of Ni:Cr steels. The first of these steels contains approximately 2 per cent Ni, C 0.15 to 0.34 per cent and Cr 0.06 to 10.25 per cent; the second, C 0.07 to 0.27 per cent, Ni 4 per cent and Cr 0 to 13.87 per cent. Cr has little effect upon the transformation points on cooling between 3 and 5 per cent.

(99) Concerning the transformation of nickel:chrome steels. M. A. Portevin. *Revue de Métallurgie*, 1917, pp. 707-716. This work is divided into (a) methods of thermal analysis, (b) influence of thermal

treatment on transformations, (c) correlation of microstructure. Ar, microstructure and hardness of a Cr:Ni steel are dependent on (1) chemical composition and initial structure, (2) rate of cooling, (3) temperature of heating, (4) pouring conditions.

(100) The penetration of the hardening effect in chromium and copper steels. L. Grenet. *J. Iron and Steel Inst.*, 1917, No. 1, pp. 107-117. Results rather than experimental data. High-chromium steels not containing Cu air-hardened with difficulty. Cr, Cu, Ni or Cu:Cr steels may be air-hardened. Copper does not prevent softening or annealing at high temperatures, but increases the depth of hardening.

(101) Chromium steels for magnets. E. Gumlich. Abstracted by *J. Iron and Steel Inst.*, 1917, No. 1, p. 411, from *Mitteilungen a.d. Physikalisch-Technische Reichsanstalt*. Tungsten having become unobtainable in Germany, chromium was used as a substitute.

(102) The influence of heat-treatment on the electrical and thermal resistivity and thermo-electric potential of some steels. E. D. Campbell and W. C. Dowd. *J. Iron and Steel Inst.*, 1917, No. 2, pp. 251-265. Two chromium steels are included in set. All explanations are advanced in terms of solution theory.

(103) The constitution of the iron:chromium alloys. Ernest Jänecke. *Z. Elektrochem*, vol. 23, 1917, pp. 49-55. Investigation of Fe:Cr alloys by cooling curves and microscope. Equilibrium diagram shows the metals completely soluble in the liquid and partly soluble in the solid state or a ternary system of Fe, Cr and Cr_xFe_y . The eutectic point is 75 per cent Cr, 25 per cent Fe, temperature 1,320 deg. C. The first solid solution is up to 55 per cent Cr and the second from 100 to 85 per cent Cr. Previous investigators used thermit mixtures and formed high-melting AlCr_4 .

(104) Physiochemical properties of Cr:Ni steel. H. J. French. *MET. & CHEM.*, vol. 17, 1917, pp. 473-476.

Properties which may be developed by the heat-treatment of certain chromium:nickel steels are recorded.

(105) Topical discussion on the use of several alloying elements in alloy steel. *Proc.*, Am. Soc. for Testing Materials, vol. 17, part 2, 1917, pp. 5-58, by F. J. Griffiths (chrome:vanadium steel, pp. 33-45). Four Cr:V steels are tabulated, giving different heat-treatments, physical properties and the difference between Ar and Ac. Results obtainable in routine commercial practice are quite uniform.

(106) The rôle of chrome:vanadium steel. R. J. Griffiths. *The Michigan Technic*, vol. 30, No. 3, 1917. A boost for Cr:V steel.

(107) The influence of chromium in steel. R. J. Anderson. *Iron and Coal Trades Rev.*, October, 1917, vol. 95, p. 439. Abstracted by *J. Iron and Steel Inst.*, 1918, No. 1, vol. 97, p. 546. Chromium does not act as a scavenger, nor does it confer soundness. In small amounts it increases tensile strength without reducing ductility; excessive amounts cause brittleness.

DURING 1918

(108) On the magnetic analysis of carbides found in different kinds of steel. T. Ishiwara. *Science Reports*, Tohoku Imperial University, first series, vol. 6, No. 5, 1918, pp. 285-294. The double carbide residue of a Cr steel and high-speed tool steel are paramagnetic, while Fe:Mn, Fe:W double carbides are magnetic and decompose at high temperatures. The decomposition of carbides into their components occurs between 650

and 730 deg. C. Residues show the presence of magnetite. Separation of cementite from eutectoid austenite on tempering begins at about 130 deg. C and ends at 380 deg. C. Temperatures of 130 deg. C., 360 deg. C. and 600 deg. C. correspond to martensite, troostite and sorbite respectively. Residue from quenched specimen contains only a small quantity of cementite, but its amount increases with the tempering temperature until it reaches 360 deg. C.

(109) On the structure of iron:carbon:chromium alloys. T. Murakami. *Science Reports*, Tohoku Imperial University, first series, vol. 7, No. 2, 1918, pp. 219-276 and twenty plates. This investigation forms the subject of the twenty-fourth report of the Alloy Research Institute. The author uses magnetic, thermal and microscopic methods in his work.

(110) Researches upon high-speed steel made at the Harvard Laboratories. M. Yatesevitch. *Revue de Métallurgie*, 1918, pp. 65-115. (Bibliography.) Deals with high-speed steels rather than Cr steels.

(111) Chromium. Samuel H. Dolbear. *Mineral Industry*, vol. 27, for 1918. (Bibliography.). Annual figures relative to price, importation and supplies of chromates and other chromium-containing products.

(112) The metallography and heat-treatment of metals used in airplane construction. F. Grotts. *CHEM. & MET. ENG.*, vol. 19, 1918, Nos. 4 and 5. Studies chromium:nickel steel (p. 195), chromium:vanadium steel (p. 241) and a special chromium steel (p. 246) analyzing 0.24 C, 0.36 Mn, 0.013 S, 0.020 P, 0.30 V and 10.44 Cr.

DURING PART OF 1919

(113) The manufacturing and working of high-speed steel. J. H. Andrew and G. W. Green. *J. Iron and Steel Inst.*, 1919, No. 1, vol. 99, pp. 305-344. Practical application of scientific methods to high-speed steel practice. These steels anneal readily if heated above critical range and slowly cooled through the lower critical point. The steel should not be heated over 1,320 deg. C., best results being obtained using temperatures from 1,300 to 1,320 deg. C. The highest secondary hardness (Brinell 610) is developed by heating between 550 and 600 deg. C. Hot work must destroy carbide envelopes occurring in the form of loops and hocks; an 88 per cent reduction on a 6-in. square ingot is necessary.

(114) The molecular constitution of high-speed steels and their correlation with lathe efficiencies. J. O. Arnold and F. Ibbotson. *J. Iron and Steel Inst.*, 1919, No. 1, vol. 99, pp. 407-435. Twelve per cent V increases efficiency of tool 98 per cent, and it can be used after a water-quench from 1,300 deg. C. Hardness and lathe efficiency are by no means identical terms.

(115) Heat-treating Cr:Ni steel with special reference to impact testing. R. C. Loudonbeck. *Steel Treating Research Soc.*, vol. 11, No. 5, 1919. Izod impact tests plotted against strength, yield point, elongation, reduction of area and Brinell hardness, showing an increase in impact value with a drop in tensile strength (136,000 to 125,000 lb. per sq.in.) and elastic limit (115,400 to 103,000 lb. per sq.in.), while the greater the elongation and reduction of area the greater the impact value. Brinell numbers vary inversely with impact. As a rule the basic steel gave better impact figures with a given set of other physical properties than did the acid steel.

New Variable Speed Power Transmission System

A SPEED control system suitable for a wide variety of uses for which variable speed power transmission is needed has been marketed by the Oilgear Co., of Milwaukee. It consists essentially of a pump which can be adjusted through a wide range of delivery capacity, and a motor driven by the work fluid—oil—received from the pump. The Oilgear variable speed drive receives power from a constant speed source, such as a line shaft, gasoline or oil engine, or constant speed electric motor, and delivers this power at any required speed from zero to a maximum in either direction, at an efficiency at full load of 85 per cent.

An infinite series of definite speed ratios irrespective of variations in load may be obtained, and there are no losses in accumulators, wire drawing through valves, etc. The power used to drive the variable stroke pump is always proportional to the power actually used by the variable speed motor. High torques are obtained at low speeds without additional power input.

The Oilgear variable speed transmission is adapted for such drives as lathes, drill presses, boring machines, etc., and machinery used in textile mills, powder mills, laundries, paper mills, cement plants and rubber mills. It is also admirably adapted to automatically controlled stokers, conveyors, gasoline cranes and excavating machinery, and to many drives where electric motors and gasoline engines are not inherently suited.

MECHANISM

Fig. 1 illustrates the motor end with the motor unit removed and shown to the left. The pump unit is identical except that it is cradled and its axis may be moved to right or left, thereby varying its displacement.

The cylinder barrel of either unit consists of a hub with central bore and five cylinders radiating therefrom. The bore of the hub is fitted closely around a ported pintle and each of the radiating cylinders contains a plunger, operated by a flat steel crosshead (hardened and ground), and delivering the plunger thrust through a roller bearing to a reaction plate on the surrounding driver. These parts are all shown at bottom of Fig. 1. As the cylinder barrel revolves each cylinder in turn registers with one of the ports as the plunger in that cylinder is moved outward, and after passing through a half revolution the same cylinder begins to register with the other port and continues to do so while the plunger is moving inward. Therefore each cylinder draws in a quantity of oil from the upper port and expels the same amount of oil into the lower port. The amount of oil handled by each cylinder at each revolution depends upon the stroke. If the operator sets the stroke at zero, no oil will be pumped. If the pump is at maximum, a large and perfectly steady flow of oil is drawn in through one of the ports and delivered through the other.

Each of these two ports communicates with a lengthwise passage through the interior of the pintle, terminating in a similar port at the opposite end of the pintle inside the case in Fig. 1. This is the motor pintle, and upon it is mounted the motor unit as described above. The oil issuing from one of the ports within the motor cylinder barrel pushes the plungers outward with whatever force may be necessary to compel the motor to rotate, and as each successive plunger reaches its outermost position, it ceases to

FIG. 1. MOTOR END OF OILGEAR VARIABLE SPEED DRIVE

register with the pressure port, crosses a bridge, and expels the oil into the return or low pressure port during the succeeding half of its revolution. Thus the five motor cylinders combine to return the perfectly steady stream of oil through the low pressure passage to be pumped over again back to the motor.

Besides the positive driving qualities of the Oilgear transmission and its perfect control of speed ratios, there is automatic protection against overload. The speeds selected by the operator are obtained irrespective of changes in load, unless the load becomes excessive, in which case an automatic overload gear relieves the operator of responsibility by preventing him from overloading the machine. The overload gear may be adjusted to any desired maximum load up to the capacity of the machine.

Boiling Linseed Oil With Electric Heat

Difficulties, disastrous fires and explosions have occurred in many cases in connection with the problem of boiling linseed oil, especially when it is used in connection with the production of linoleums and oilcloths.

F. J. Ryan & Co., Wesley Bldg., Philadelphia, Pa., has completed both the installation and test of a new boiling method using electric heat, which besides doing away with the distinct disadvantages of the old method has made possible complete heat and chemical control over a very wide range of temperatures involved.

This installation was made at the works of the Armstrong Cork Co., Linoleum Section, Lancaster, Pa. The installation is of considerable size, having a connected load of 75 kw. and handling batches of 2 tons of material at each heat. In approaching the problem it was necessary to consider the inherent characteristics of linseed oil to build up heat within itself during the oxidation period, and the fact that viscosity changes materially within very narrow temperature range, necessitating definite and exacting control.

The heating method applied is indirect and therefore the temperature of the ribbon is necessarily considerably higher than that desired in the oil. This necessitated a special cooling system to reduce the exterior heat to the normal oil requirement, when stopping the furnace to hold for processing.

General Electric heating units and Leeds & Northrup control are used, while the main furnace body and appliances for operating were constructed at the works of the Lancaster Iron Works, Lancaster, Pa., which is associated with the Ryan company.

Book Reviews

HEAT-TREATMENT OF SOFT AND MEDIUM STEELS.

By *Federico Giolitti*, Bessemer Medalist. Translated from the Italian by E. E. Thum, Associate Editor, *CHEMICAL & METALLURGICAL ENGINEERING*, and D. G. Vernaci, Metallurgical Engineer; 374 pp., 6 x 9; 214 illus. Price \$5. New York: McGraw-Hill Book Co., Inc.

Dr. Giolitti's book is probably unique in its field, in that the author has set himself the task of writing a treatise for the use of practical men which explains, as fully as the present state of metallurgical knowledge permits, the mechanism of the solidification of steel, in order that the reasons for the different heat-treatments described may be truly understood by the reader. In a general way, every one who practices heat-treatment understands that heatings above the critical range and below the solidus promote diffusion of the carbon and other elements in the steel, and hence are the first step necessary in heat-treatment, their function being to substitute homogeneity for its opposite in both forged and rolled steels. We all realize, too, that to retain the homogeneous state attained during this first heating comparatively rapid cooling is essential, and that to relieve the stresses set up and to reduce the hardening due to this rapid cooling a second heating is necessary, generally at a temperature below the critical range.

Of the 360 text pages of the book, the first 101 are devoted to a discussion of the phenomena of solidification and of transformation of the freezing and cooling steel, and an attempt is made to show and explain diagrammatically the reasons for and the extent of the heterogeneities of chemical and physical composition resulting from solidification of the metal and its transformation in cooling through the critical range. The author is not content with diagrams in two dimensions, but soon carries his reader into three, and even into more complicated figures in which by a sort of process of compromise the steels containing four, five or more variables can be reduced to a three-dimension diagram.

This part of the book is very heavy reading and quite beyond the mental grasp of a great many, perhaps a majority, of so-called "heat-treaters"—indeed no one but a thoroughly trained theoretical metallurgist could follow the explanations intelligently. Inasmuch as our present knowledge is still not nearly complete enough to allow numerical values and definite locations to be assigned to these various curves and surfaces, one is tempted to ask oneself if after all the effort to follow all this complicated reasoning has been worth while. Indeed, the author himself is apparently troubled by the same doubts.

Having, in parts I and II, chapters 1 to 10, covered these purely theoretical considerations, the author proceeds, in part III, chapters 11 and 12, to discuss the selection of the heat-treatments best suited to break up the initial heterogeneity of the steel, and to explain somewhat in detail the reasons underlying such selections, these chapters, as indeed is true of all the rest of the book, frequently referring back to discussions contained in the first two sections. Chapter XIII then discusses two groups of phenomena which modify the effects of these heat-treatments that are designed to reduce heterogeneity (for which the author has coined the phrase "preliminary" heat-treatments, as contrasted to the subsequent heatings to lower temperatures, which he styles "final" or "quality" heat-treatments). These two groups of phenomena are those arising during rolling, forging, etc., and those due to solid non-metallic inclusions.

In this chapter we learn the disquieting fact that steels containing certain classes of inclusions cannot be heat-treated in such a way as to make them the equal of metal free from these undesirable parasites. The underlying cause of this is stated to be "the state of oxidation in the system, or better, the oxygen pressure of the non-metallic particles and of the metal respectively, and from the variations which this ratio suffers during crystallization and the subsequent cooling." A series of experiments, the author states, makes this fact practically certain, and for the

description of these experiments one is referred to Italian work and to a forthcoming article in *CHEMICAL & METALLURGICAL ENGINEERING*. It is unfortunate that these data should not have been included in the present volume, as the mere statement of fact leaves the reader who has not read the articles in question unconvinced. Examples are given showing the connection between inclusions and "streaked" or "woody" fractures in transverse test-bars of forged steel. In later chapters this subject is taken up again, when considering transverse strength.

In part IV, chapters 14 to 18 inclusive, the heat-treatment of cast steel is discussed in great detail. Perhaps the most interesting part of these chapters is that which explains the relationship between the primary or dendritic structure and the secondary or network structure of cast steels. It is shown that while the latter structure can be broken up by comparatively simple heat-treatments, the primary or dendritic structure is very persistent and can be broken up only by repeated heatings and coolings. It is shown also that although a fibrous fracture, indicating considerable toughness, is produced in tension specimens by the more simple treatments which break up only the ferrite network, in the impact tests only the specimens that have undergone the more complex treatments designed to break up the dendritic structure show a fibrous fracture.

The arrangement of these tables of tests and heat-treatments is not good, as the reader is constantly forced to refer back a number of pages in order to refresh his memory as to the heat-treatments to which the various specimens in the tables of tests have been subjected. To the metallurgist who is familiar with the heat-treatment of cast steel, too, there appears to be far too wide a gap between the two classes of heat-treatments described—the simple ones that do not affect the dendritic structure, and the complex ones that do. It is by no means clear, and indeed in the reviewer's opinion is not a fact, that recourse need be had to such complicated and drastic treatments to attain this desirable effect.

The very interesting fact is brought out in these chapters that in very low-carbon cast steels the dendritic structure is only slightly developed, so that quite simple heat-treatments suffice to give these steels comparatively good physical properties. Further, it is shown clearly and convincingly that medium-carbon cast steels cooled slowly after the preliminary annealing develop a coarse microstructure and correspondingly poor physical properties, indicating the desirability of more rapid cooling, as in air, oil or water, followed by proper reheating, if the best physical properties are to be attained.

An important discussion in these chapters is that in which it is shown that cast medium-carbon nickel steels develop this coarse microstructure on cooling after the preliminary heat-treatment far less readily than do simple steels, so that an air-cooling of the nickel steel is roughly the equivalent of a quenching of the carbon steel—a fact of great importance in the heat-treatment of castings of large size. Many data are given showing the excellent physical properties that can be obtained with mild nickel steel castings suitably heat-treated.

Unfortunately, though the author does not hesitate to give many pages of data and tests showing the truly remarkable results attained in the Italian plant with which he is connected in the manufacture of these castings, he does not feel at liberty to reveal the exact heat-treatments to which the various castings described were subjected in order to give them these fine physical properties. This seems a most unfortunate omission, as it looks far too much like boosting the goods of a foreign maker in a scientific treatise.

Chapter 18 is devoted to the effect of non-metallic impurities upon the behavior of cast steel in heat-treatment, and we are again reminded that badly made steel does not respond properly to even the most scientific heat-treatment—the explanation, as before, being couched in more scientific language.

Part V, chapters 19 to 22 inclusive, deals with the heat-treatment of rolled and forged steels. Consideration is given to the manner in which preceding hot-work modifies the effect of heat-treatment upon the steel; and the close connection between lamellar structure in rolled steels, which

gives rise to transverse weakness and ingotism in cast steels, is pointed out. The same heat-treatments, therefore, that will eliminate ingotism in cast steel tend to improve the properties of rolled or forged steel, especially when tested transverse to the direction of rolling. Mention is made also of the marked effect of cold-work upon subsequent heat-treatment, due to grain growth during the annealing.

Tables and data are given and discussed showing that forging before heat-treatment is of less value in the case of steels of compositions suited to use as castings than in the case of other compositions not suitable for cast steel. A very interesting section is devoted to the effects of heat-treatment on pieces of steel of large mass, and the author points out the desirability of using for these heavy forgings steels whose transformation points are lowered and whose thermal hysteresis is increased by the use of suitable alloys. In the case of certain of these alloy steels, heavy forgings can be heat-treated without rapid cooling and yet show fine microstructure and good physical properties throughout their cross-section, whereas ordinary steels so treated retain in their inner portions a very coarse microstructure, with correspondingly poor physical properties. This is, of course, of great value in the case of forgings so heavy that they cannot be quenched without liability of cracking.

The last two chapters, in which are considered the effects of heat-treatment upon the longitudinal and the transverse properties of steel, are perhaps the most interesting part of the whole volume.

Data are given to show the desirability of using alloy steels that can be heat-treated without quenching with results practically as good as those obtained by quenching of simple steels, a procedure that enables the steel maker to give first class physical properties to forgings and to castings of such shape and design as to make quenching dangerous. The great difference between the longitudinal and the transverse properties of rolled steels is discussed at length, and the difficulty of so heat-treating rolled and forged steels as to obtain really good transverse properties is emphasized. Mention is made also of the importance of so designing vital parts and so carrying out the forging of them as to prevent their being subjected in service to heavy stresses in a direction transverse to the direction of forging. The reader is again reminded of the virtual impossibility of so heat-treating steel containing certain kinds of inclusions that it will show really good properties when tested transverse to the direction of rolling or forging, and the book concludes with the following paragraph, which at first sight sounds revolutionary, though after carefully reading the whole work its truth appears undeniable:

"It follows that in many cases, and above all when it is impossible to forge the piece in such a way that the working stresses fall in a longitudinal sense, *the rational employment of heat-treated steel castings may present relevant advantages in comparison with steel forgings*, not only from the viewpoint of rapidity of construction but also of resistance to stresses and its immunity from accidental fragility." (The italics are the reviewer's.) To one who, like the reviewer, has preached for years the advantages of real heat-treatment of steel castings for severe service, this paragraph brings a peculiar satisfaction.

The volume includes a brief bibliography of books bearing upon the subject under discussion, and references to other books and articles by the author, some of which give in more detail the discussions necessarily abbreviated in the present volume.

The work of translation has been ably done, so that in no instance has the sense of a paragraph or sentence been obscured. It is embarrassing, however, to the American reader to have the dimensions of castings and forgings given almost in every case in metric figures. With this exception and the above-mentioned fault in the arrangement of some of the tables of heat-treatments and physical properties, the presentation of the data is extremely good.

The work should be of the greatest value to the technically trained metallurgist, and though a good deal of the purely theoretical matter is probably beyond the grasp of the practical heat-treater, yet he too can obtain much most valuable information from the detailed discussions of the various heat-treatments.

JOHN H. HALL.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Platinum Substitute.—James B. Grenagle, of Catonsville, Md., has patented an alloy which is claimed to be adapted for use in laboratory apparatus and for other chemical and electrochemical purposes for which platinum is commonly used. The alloy contains 60 to 90 per cent of molybdenum and 40 to 10 per cent of tantalum; it has a melting point above 2,000 deg. C., has a high tensile strength, is ductile and malleable, and is highly resistant to the action of ordinary chemical reagents. (1,385,072; assigned to the Rare Metals Reduction Co., of Baltimore, Md.; July 19, 1921.)

Nitrostarch Explosives.—In the production of nitrostarch, as with other explosives, it is desirable to obtain great strength with a maximum insensibility to blows or friction. It is known that the explosive strength of nitrostarch is not materially decreased by the presence of a limited amount of water, and, in fact, owing to the intense heat produced at the instant of explosion, this water actually serves to increase the volume of gas which is produced. In order to prevent evaporative drying of the wet nitrostarch, Walter O. Snelling, of Allentown, Pa., assignor by mesne assignments to the Trojan Powder Co., of New York, proposes to add a deliquescent inorganic salt such as ammonium nitrate. Such a mixture might contain 50 per cent of nitrostarch, 40 per cent of the deliquescent ingredient and 10 per cent of water. (1,386,437; Aug. 2, 1921.)

Such a mixture may, however, be subject to some hydrolysis with subsequent decomposition and loss of stability. The presence of zinc oxide or hydroxide has been found effective in preventing this hydrolysis and Snelling in a second patent (1,386,438) adds 1 per cent to 5 per cent of such a zinc compound to the explosive mixture.

Another patent by the same inventor relates to the manufacture of nitrostarch explosives without recourse to the usual drying operations. The wet nitrostarch containing as much as 25 per cent of water is treated with a concentrated solution of ammonium nitrate and then centrifuged. In this way it is possible to substitute the ammonium nitrate solution for the water in the nitrostarch. Mixing this product with equal weight of dry ammonium nitrate one obtains a mixture which contains 37.5 per cent of nitrostarch, 56.25 per cent of ammonium nitrate and 6.25 per cent of water. This mixture is sensitive to commercial detonators and forms a highly desirable explosive (1,386,439; Aug. 2, 1921.)

Manufacture of Alum Cake.—Dr. Richard Moldenke, of Watchung, N. J., has recently been granted a patent for an improved method of producing alum cake—i.e., the commercial hydrated aluminum sulphate. It is claimed that the process yields a relatively pure product, free or nearly free from iron, and without an excessive loss of acid. Bauxite, clay or any other mineral containing alumina is finely ground and then mixed with sufficient strong sulphuric acid to form a paste or slurry. This paste is vigorously agitated at a high temperature (500 to 600 deg. F.) in an atmosphere of acid vapor in order to form aluminum sulphate and to prevent hardening into a cake or mass. After the reaction is completed the finely grained product is mixed with the amount of water necessary to make the crystallized aluminum sulphate. Under these conditions, a hot liquid mixture is obtained which can be readily separated from accompanying undissolved sand, clay, iron oxide, silica, etc., by simple filtration or settling. After removal of these insoluble residues, the clear liquid on cooling sets to a hard, crystalline, commercial cake. With care in the operation, this cake is practically free from iron. (1,388,436; Aug. 23, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Organic Chemical Manufacturers Form Association

Manufacturers of organic chemicals on Oct. 29 perfected a trade association after intensive consideration of the subject during two days' meetings in Washington. Dr. Charles H. Herty has resigned as editor of the *Journal of Industrial and Engineering Chemistry* to accept the presidency of the new organization, which is to be known as the Synthetic Organic Chemical Manufacturers' Association of the United States. The purposes of the organization, as set forth in the constitution, are:

To advance the science of organic chemistry by encouraging the manufacture in the United States of all kinds of organic chemicals; to co-operate with the various agencies of the Government of the United States in its efforts to develop, improve and render serviceable a complete organic chemical industry; to promote cordial relations between American concerns and individuals engaged in the production and use of organic chemicals; to afford means for the dissemination of scientific knowledge; to promote the highest scientific and business standards in relation to the industry; and generally to take such collective action as may be proper for the establishment and perpetuation of the organic chemical independence of the United States of America.

The determination to secure Dr. Herty for the presidency of the association was reached late Friday night. Dr. Herty was at the Cosmos Club and had retired when the presence of a committee of manufacturers to wait upon him was announced. He rose to receive the committee and at first was determined not to accept the position offered him. The reasons that actuated him to change his mind are set forth in the following formal statement issued by Dr. Herty:

At last there has been brought together one effective organization of men who, for the past five years, have been developing in this country all lines of manufacture of synthetic organic chemicals. The fine spirit shown throughout the meetings gave assurance of a strong organization which will aid in developing to its maximum efficiency this industry born of the war period and now recognized by all as being of such fundamental importance to the nation. Much progress has been made, but there is a long road ahead before we can hope to give to our country an industry which can worthily meet its every need. Toward that goal we are facing.

The association as organized is thoroughly democratic in character. It follows national lines in this respect, for in the councils of the association the small manufacturer has equal voice with the larger and we all recognize that the success of the industry is closely bound up in the welfare of the small manufacturer. There have been some points of friction in the past between producer and consumer, but I believe that the hearty spirit of co-operation is developed which in the end will assure the future of this industry.

Personally it seems strange to me to be leaving the ranks of the chemists for those of the manufacturers. For six years I have editorially striven to arouse first the chemist and then our people in general to the importance of developing this industry. The idea is now so clear to all that I feel my best efforts can be given to work with the manufacturers on their many problems in the hope of aiding them in the firm establishment of that industry which is so vitally important to this nation that Secretary Hoover, while emphasizing that the main consideration now was the development of this industry for utilization of waste, nevertheless added:

"In these days of the development of forms of warfare that we have to exist under, it is fundamental and vital to us that we should maintain those industries on which we are bound to depend for our very vital existence if we ever come to conflict."

It was stated that the association is in no way a rejuvenation of the Dyes Institute and is not absorbing that organization. The new association is divided into four sections: Dyestuffs, Pharmaceuticals, Intermediates and Fine Organic Chemicals. Each section will have a vice-president, a secretary and an executive committee.

A board of governors, consisting of the president, the four vice-presidents and ten members to be nominated by the sections, will be the administering body of the association. C. N. Turner was selected to be the Dyestuffs vice-president; Herman Seydell, the Pharmaceutical vice-president; S. W. Wilder, the Intermediate vice-president and B. T. Bush, the Fine Organic vice-president. Six other members of the board of governors were chosen as follows: R. S. Burdick, R. C. Jeffcott, August Merz, M. R. Poucher, P. Schleussner and F. P. Summers. The remaining four members, one from each section, will be chosen later.

Dean Cooley Discusses the Problems Facing the F.A.E.S.

During his first visit to the headquarters of the Federated American Engineering Societies since his election to the presidency of the organization, Dean Cooley announced his conclusion that the most necessary thing to do first is to tune up the existing machine so that it may be in the best working order to accomplish the multiplicity of tasks that are before it. Engineers are foremost, he says, in the actual service rendered the public, but the amount of public service they are capable of rendering can be increased immensely if the Federation can co-ordinate and direct the vast energies of the nation's engineers. The public already has been sold the idea of the Federation, Dean Cooley believes, but he thinks much education and hard work will be required before the Federation can be sold to the engineers themselves.

There is scarcely a limit to what engineers can do if they will really work to a common end, says Dean Cooley. Even if they were to limit themselves to efforts to stabilize industries and to eliminate waste, they could perform a national service of first magnitude and indirectly benefit themselves immeasurably, he believes. Only a little progress along these lines would have to be made before unemployment among engineers would disappear, in his estimation.

Dean Cooley points out that it is well understood why engineers, as a whole, have so few collective accomplishments to which they can point. It goes back to the schools, he says, where there is failure to give the engineer a well-rounded education. As a result, he stays within the narrow boundaries of his specialty. With the example of the spirit and point of view of such engineers as Herbert Hoover, Dean Cooley believes there is going to be a general breaking away from the meshes of technicality and that engineers are going to utilize the ability they already possess as economists and business men and become men of affairs.

Priestley Portrait Presented to National Museum

A copy of the Stewart portrait of Joseph Priestley was presented to the National Museum in Washington on Oct. 25 by Dr. Edgar F. Smith on behalf of the American Chemical Society. In making the presentation Dr. Smith told how Priestley, with the help of Washington and Jefferson, did much to stimulate the establishment of chemical industries in this country.

Disposal of British Government Surplus Chemicals

It is reported from London that the Disposal and Liquidation Commission has entered into a contract with Charles Tennant & Co., Glasgow, for the disposal of unsold chemicals and explosives on a commission basis.

More Plants Resuming Operations

Glassware. The American Window Glass Co., Monongahela, Pa., has resumed operations at its local plant after a shut-down for nearly a year. It is said that orders on hand insure continuous production for an indefinite period.

The Thatcher Mfg. Co., Kane, Pa., manufacturer of milk bottles, is increasing the working force at its local plant.

The DuBois Glass Co., Falls Creek, near DuBois, Pa., manufacturer of glass bottles, is making a number of improvements in its plant, including the installation of new equipment, and is said to be planning for a resumption of production at an early date. The works have been closed for many months.

Ceramic. General ware potteries in the eastern Ohio district have increased production to a point of about 75 per cent of normal, the most active schedule attained during the present year. A number of plants are operating at normal.

The National Fireproofing Co. has resumed production at its plant at Keasbey, N. J., for the manufacture of fire-brick, following a shut-down for about eight months past. The plant has been equipped for electric operation and steam power will be abandoned. It is expected that a full working force will be employed at an early date.

The Jackson China Co., Falls Creek, near DuBois, Pa., has resumed operations at its pottery after being closed down since early in the year.

Chemical. The Keeler Chemical Co., Wetmore, Pa., manufacturer of methanol, acetate of lime, etc., is planning for the resumption of production at its plant early in November, after being idle since the first of the year.

Coke. The Mount Pleasant Coke Co., Carpentertown, Pa., has fired 310 coke ovens at its plant, following a shut-down since early in the year.

Steel. The Cumberland Steel Co., Cumberland, Md., has resumed full time production at its local plant, with curtailed working force, following a half-time operating schedule dating from last February.

The Parkersburg Iron & Steel Co., Parkersburg, W. Va., has resumed operations at its local mills after an idleness of a number of months. About 500 men will be employed.

The Alan Wood Iron & Steel Co., Conshohocken, Pa., has resumed operations at its open-hearth department, following a shut-down for a considerable period. Three furnaces at the Ivy Rock plant have been placed in service.

Paper. The Hinde & Dauch Paper Co., Muncie, Ind., has resumed production at its local mill with about sixty operatives, or approximately one-fourth of the regular working force. It is planned to increase the number of employees gradually. The mill has been closed for a number of months.

Miscellaneous. The Viscoloid Co., Leominster, Mass., manufacturer of celluloid products, has adopted a night operating schedule in certain departments of its plant.

The Yaryan Rosin & Turpentine Co., Brunswick, Ga., has resumed full time operations after an extensive curtailment dating from last February.

William M. Burton Chosen as Perkin Medalist

At a meeting of the Perkin Medal Committee of the Society of Chemical Industry, held at the Chemists' Club, Oct. 24, William M. Burton, president of the Standard Oil Co. of Indiana, was awarded the medal for 1921-1922. The formal presentation will be made Jan. 13, 1922.

Mr. Burton's work in the field of pyrolytic distillation of petroleum has brought him international fame. There are now in use in the United States about 2,000 stills in which his patented process is employed, producing in the neighborhood of 1,000,000,000 gal. of gasoline per year, in addition to the gasoline produced normally from crude oil. This amount represents from 20 to 25 per cent of the total gasoline produced in the United States.

Mr. Burton also observed that as a byproduct of the process there was produced an artificial asphalt which was practically identical with Trinidad asphalt from a chemical standpoint and also for practical use. Such asphalt is now widely used for road building, roofing and paving purposes.

The Business Publishers and Editors Meet in Chicago

The National Conference of Business Paper Editors and the Associated Business Papers, Inc., met in annual convention at Chicago on Oct. 24, 25 and 26. The central theme of the convention was the revival of business and what business papers can do to speed it along. The keynote speech for the publishers' convention was given by Mr. James H. McGraw, president of the McGraw-Hill Co., who pointed out that the task of interpreting the world's condition to American business must be assumed by business paper editors and publishers. The outstanding feature of the editors' session was a discussion of the relation between the Department of Commerce and the business papers by F. M. Feiker, assistant to Secretary Hoover. Mr. Hoover had himself hoped to be present to address the conference, but found it impossible to do so. The following telegram was received from him as evidence of his confidence in the business press and the importance of the work of the National Conference of Business Paper Editors:

Pressure of official duties makes it impossible for me to address the members of the National Editorial Conference in Chicago, as I should like to do. I have appreciated the opportunity given me in the monthly meetings we have held together in Washington to express the policies of the Department of Commerce with regard to some of the pressing industrial questions before us. We have indeed great problems yet to solve. I cannot but feel that if these problems are considered as human and not as material questions, we can find their solution. We are dealing with questions of railways, of farms, of shops and of instruments of commerce and industry, but in the background of every person's mind there is the fact that we are dealing not with mechanical things but that we are concerned with the problems of men, women and children. There must be in our discussions of these matters the dominating thought that the better control of economic forces is in fact simply the better comfort of the country. Those several organizations within the Department of Commerce which we have developed and set at work within the past few months are concerned in this spirit, and it is a fine augury of our industrial future to know that the programs and purposes of these various departmental activities have come from our manufacturers, merchants and engineers themselves. The editors of the business press have shown a fine spirit of service. Your opportunity for leadership is unique and unchallenged. Upon you rests in large measure the responsibility of the control of industrial thought and opinion in the detail of the industrial, economic and technical problems which confront us. I wish your conference every success in carrying forward your high and constructive purposes.

The editors presented a résumé of conditions in the following basic industries: Iron and steel, railroads, marine, automotive, textiles, electrical, construction industries, mining, leather and agriculture. In general they indicated a slight improvement in business and an optimistic outlook. All felt that the bottom had been reached and that business is on the upward trend. No more hopeful picture of any industry was painted than of agriculture, which is generally supposed to be in the dumps.

At the election of officers James H. McGraw was chosen president of the Associated Business Papers. The editors elected the following group: C. J. Stark, *Iron Trade Review*, president; H. C. Parmelee, *CHEMICAL & METALLURGICAL ENGINEERING*, vice-president; W. W. Macon, *Iron Age*, secretary and treasurer. The following comprise the executive committee: A. I. Findley, *Iron Age*; V. E. Carroll, *Textile World*; S. O. Dunn, *Railway Age*; Harry Hilman, *Inland Printer*; James H. Stone, *Shoe Retailer*, and C. A. Moffat, *Druggists' Weekly*.

Leather Manufacturers Vote Against Cod Oil Tax

The board of directors, New England Shoe and Leather Association, Boston, Mass., has adopted resolutions protesting against the imposition of a tax on Newfoundland cod oil. It is held that this is essentially a raw material, requires no protection and that any tax will raise unnecessarily the cost of leather and leather products.

Meeting of Chicago Section A.C.S.

Friday, Oct. 21, was the occasion of the second monthly meeting of the Chicago Section of the American Chemical Society. With the increased interest in so many industries in hydrogen-ion concentration it was particularly timely that Dr. Paul E. Klopsteg of the Central Scientific Co. should speak at this meeting on the practical aspects of electrometric methods in chemistry. As a physicist of note, his work in co-operation with Dr. Wendt in the development of apparatus has been of distinct service not only to the research laboratory, but of still more importance to many scientifically controlled industrial operations.

Following the paper by Dr. Klopsteg, Dr. Wendt led a brief discussion on the method of operating the apparatus exhibited. Dr. Hale of Michigan, speaking for the Chemical Foundation, made some rather startling revelations concerning the extent of German competition in the dye manufacturing and consuming industries. Dr. H. E. Howe, who was a visitor, spoke briefly on the aims of the National Research Council.

The group meetings following the main address were enthusiastically carried forward on the following subjects:

Groups 1 and 2 (Laboratory Methods). Subject: The Electrolysis of Lead Tartrate Solutions. Leader: V. H. Gottschalk, of the Western Electric Co.; Subject: Determination of Free Alkali in Soap. Leader: M. L. Sheely, of the Armour Soap Works.

Group 3 (Synthesis). Subject: Synthesis of an Organic Arsenic Compound. Leader: H. C. Cheetham, of Northwestern University.

Group 4 (Biologic). Subject: Animal Biologic Derivatives. Leader: David Klein, of the Wilson Laboratories.

Hearings on River and Harbor Pollution Legislation

Drastic legislation in an effort to prevent pollution of waters in rivers and harbors probably will be recommended to the House of Representatives in the near future. This may be judged from the attitude of members of the House Committee on Rivers and Harbors during the course of the hearing on bills intended to prevent pollution of waters. John I. Tierney, representing the Manufacturing Chemists' Association, appeared before the committee and urged that before a step was taken which would interfere greatly with a large number of manufacturing plants the Secretary of Commerce be requested to conduct a scientific investigation as to the causes of water pollution. He told the committee that the discharges from chemical plants had very little effect on animal and vegetable life. He thought chemical manufacturing plants are being blamed in some cases for damage done by acid waters from coal mines.

While witnesses for the bill were able to show actual and material damage caused by the indiscriminate discharge of petroleum sludge from tank-ships, they were admittedly without specific data as to the damage done by the discharges of waste materials into streams from manufacturing plants. Mr. Tierney called the attention of the committee to the fact that the witnesses had presented no actual data showing that chemical waste had caused damage. He declared that Congress owes it to the industry not to interfere with the operation of its plants until properly qualified engineers should have made a study of the problem.

The committee may attempt to give some protection to manufacturing plants in the bill it will report, but apparently it is bent upon pressing legislation at this time which will affect materially the interests of all industries which discharge waste into streams.

French Imports of German Potash Cause Concern

Prominent men in the French potash industry express much concern over the large importations of potash from Germany. Despite the duty of 30 fr. per ton on chloride of potassium, German salts can be sold cheaper than the French product. The matter has been reported to the government.

Measurement of Color in Industry

At the regular monthly meeting of the Delaware Section of the American Chemical Society, held in Wilmington on Wednesday evening, Oct. 19, Dr. A. H. Pfund of Johns Hopkins University spoke on "Measurement of Color as Applied to Industrial Needs." The speaker's first work along this line was on lithopone paints. Practically all the so-called white paints have an outstanding tint, and by means of multiple reflection he has been able to accentuate this tint and to measure it.

In ordinary colorimetry and photometry the sensibility cannot be greater than that of the unaided human eye, and it has been found that the average physiological sensibility is only about 2 per cent. This, of course, is not accurate enough for quantitative work. The speaker pointed out that any color can be expressed absolutely by the three factors: brightness (or reflection coefficient), saturation and dominant hue. The first two are ratios or percentages, and the third is a definite wave-length. In order to express colors in this manner there must be marked improvement in the sensibility of the colorimeter.

Working along this line, Dr. Pfund has been successful in developing a differential tintometer. So far he has studied more particularly the comparison of two dyed skeins in order to check the dye-tester's judgment. The two samples are mounted at the ends of a track upon which slides a small nitrogen-filled electric bulb. Light from the two samples is reflected through a colorimeter tube to an eye-piece. The light source is moved along the track until the brightness of the two halves of the colorimeter field appears the same. By twisting one sample and thus increasing the reflection from it, the saturation or "strength" of the two samples is equalized. Then the two samples are interchanged. If they really are the same, the field will not be affected, but if they are not the same, there will be a marked difference. This device doubles the sensibility of the human eye.

In order to compare the dominant hues of the two samples, advantage is taken of the fact that the human eye is most sensitive to a certain hue in the purple. Color screens are introduced into the eye-piece so that, regardless of the actual hue of the sample, the light reaching the eye is purple. Here again the sensibility is doubled by interchanging the two samples. The color screens consist of an exceptionally ingenious arrangement of wedges, by which any desired wave-length can be transmitted or absorbed. The great sensibility of this differential tintometer was shown by a demonstration in which skeins that had been judged "O. K." by an expert dye-tester appeared to be markedly different when compared in the instrument.

Confer on Muscle Shoals

Following a conference on Muscle Shoals in Washington Oct. 24 among the Secretary of War, the Secretary of Commerce, Brigadier General Harry Taylor, W. B. Mayo and Colonel J. W. Worthington, Secretary Weeks declared that definite progress is being made and that the spread between the estimates of the Army engineers and the Ford engineers on the cost of the completion of the Wilson dam and the construction of dam No. 3 has been narrowed materially. Secretary Weeks stated that no bargaining was attempted at this conference, as that would be done between Mr. Ford and himself shortly after he has looked over the project personally, but his attitude indicated plainly that he is much more favorably impressed with the proposition in its present form than at any previous time.

Secretary Weeks left Washington Oct. 25 on his Southern trip and his plans included a personal inspection of the Wilson dam and the nitrate plants. Shortly after his return to Washington he expects to "get down to figures" with Mr. Ford.

German Company to Resume Manufacture of Fertilizers

The Badische Anilin und Sodafabrik announces that it will resume the manufacture of nitrogenous fertilizers in about three months.

Personal

Dr. V. L. BOHNSON has been promoted to an assistant professorship in general chemistry at the University of Wisconsin, Madison, Wis.

CHARLES FRÉMONT, who was awarded the Bessemer Gold Medal of the British Iron and Steel Institute, began to contribute to French technical literature in 1890. He is best known abroad through his researches in metallurgy and the strength of metals, especially iron and steel, and the apparatus invented by him for testing steel by shock. Besides the Bessemer Medal, he has also been awarded (in 1920) the great gold medal bearing Prony's effigy, by the French Société d'Encouragement pour l'Industrie Nationale, two great gold medals by the Société des Ingenieurs Civils de France (in 1897 and 1898), and over thirty prizes by the French Academie des Sciences and the Société d'Encouragement. M. Frémont is ingénieur-constructeur, chief of the mechanical laboratory of the French Ecole Nationale Supérieure des Mines, member of the Commission des Méthodes d'Essai des Matériaux de Construction in the French Ministry of Public Works, etc.

FEDERICO GIOLITTI arrived in the United States on Oct. 20.

Dr. WILLIAM J. HALE of the Dow Chemical Co. spoke before the Mining Congress on "Protecting American Industry."

WHITNEY S. HAMNETT, who was for twelve years with the Pittsburgh Testing Laboratory, eight of which were as manager of the Dallas (Tex.) branch and the last two as Eastern manager of the company at New York, has resigned, and has become associated with J. E. Dockendorff & Co., New York, American agent for two manufacturers of aluminum in Switzerland.

Dr. H. B. HART has been appointed research chemist for the Eagle-Picher Lead Co., Joplin, Mo.

W. LEE LEWIS, director of chemistry of Northwestern University, addressed the Chicago Chemists Club on Oct. 25 on "Joaquin Miller, the Poet of the Sierras."

E. P. MATHEWSON has gone to Burma, via Continental Europe. He expects to remain several months in the Far East studying metallurgical practice at the mill and smelter of the Burma Corporation.

W. R. OGLESBY, formerly with E. I. du Pont de Nemours & Co., is now vice-president of the American Food Products Corporation, New York City.

H. C. PARMELEE was a guest at the Chicago Chemists Club last week.

EDGAR F. SMITH addressed the American Mining Congress banquet in Chicago on Oct. 21.

C. E. WATTS, Steelton, Pa., chemist of the coke-oven department at the local plant of the Bethlehem Steel Co., was tendered a farewell dinner on Oct. 13 at Folger's Inn, Dauphin, Pa., by executives and associates at the works, on the occasion of his departure to West Virginia to take up work at the Bethlehem company's mines in that district.

The National Conference of Business Paper Editors, which recently met at Chicago, elected the following officers for the ensuing year: C. J. Stark, *Iron Trade Review*, president; H. C. Parmelee, CHEMICAL & METALLURGICAL ENGINEERING, vice-president; W. W. Macon, *Iron Age*, secretary-treasurer. The following comprise the executive committee: A. I. Findley, *Iron Age*; V. E. Carroll, *Textile World*; S. O. Dunn, *Railway Age*; Harry Hilman, *Inland Printer*; James H. Stone, *Shoe Retailer*, and C. A. Moffat, *Druggists' Weekly*.

The executive committee of the National Safety Council elected the following vice-presidents for the National Safety Council: David S. Beyer, Liberty Mutual Insurance Co., Boston, vice-president for service to members; B. F. Tillson, New Jersey Zinc Co., Franklin, N. J., vice-president for industrial safety; F. A. Davidson, Dwight P. Robinson Co., New York City, vice-president for sectional activities; C. B. Scott, Bureau of Safety, Chicago, vice-president for local

councils; David Van Schaack, Aetna Life Insurance Co., Hartford, Conn., vice-president for public safety; W. E. Worth, Chicago Safety Council, secretary and treasurer. W. H. Cameron, formerly secretary-treasurer of the National Workmen's Compensation Service Bureau, New York City, was elected executive secretary of the National Safety Council. Sidney J. Williams was re-elected chief engineer of the Council. C. W. Price, formerly general manager, will assist the National Safety Council as a special consultant in public safety. The executive committee approved the organization of a Drop Forge Section and a Petroleum Section by the companies in its membership interested in more intensive accident prevention activities in those two groups of industries.

Obituary

JESSE PETERSON, seventy-one years old, a fiber products manufacturer, died in Lockport, N. Y., on Oct. 22 of heart disease. Mr. Peterson was one of the first fiber manufacturers in America and organized the United Industrial Fiber Company in 1889.

CHARLES W. WHITLEY, vice-president of the American Smelting & Refining Co., New York, and in charge of the company's plants in the United States, died on Oct. 9.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Oct. 31, 1921.

The chemical industry during the past week was quite active and buying orders reached the market in good volume. On some commodities producers had to withdraw and wait for revised prices. Some of the largest alkali plants have gradually reduced their overhead and are reported working at capacity. The Solvay process plant of the Allied Chemical & Dye Corporation reported a rapid rise in demand for its products and this has caused production in all the company's departments to approach normal levels. Other leading plants have increased working capacity and it seems probable that the turn of the year will find the chemical industry on a stronger footing than at any time since the recent depression. Consumers have come into the market with greater interest and frequently desired to increase standing contracts.

The threatened railroad strike has at last been averted. It cannot be truthfully said that this unsettled condition has been the cause of a revival of active trading, but it has helped the market along to some extent, as consumers feared being left with empty shelves and those who had been accustomed to the hand-to-mouth method of buying were eager to buy well in advance. Market prices have reflected the marked increase of buying operations and in some instances the spot market was held at a war-time premium. Forward shipment business has also shown an increased interest.

The export trade is showing signs of improvement. Importations of English and German chemicals have not had a tendency to weaken standing quotations. Imported bleaching powder and prussiate of soda attracted considerable attention. Increased sales and inquiries were noted on sal ammoniac and cyanide of soda and prices were advanced accordingly. A better demand was also recorded on sulphuric and oxalic acids.

CHEMICALS

Dealers were offering spot *acetate of soda* at 4c. per lb., but might shade prices a trifle on firm round lot business. Leading manufacturers were asking up to 4½c. for prime goods and quoted lesser quantities at 4¼c. per lb. The

demand for this product has not been very active and business has passed for small lots only. Sales of spot *bichromate of soda* were reported at 8@8½c. per lb. It is possible that an odd lot might be picked up at 7½c., but the greater portion of dealers were above this figure. Offerings around the trade were not heavy and the tone of the market appeared very firm at the close. *Solid caustic soda* is attracting considerable attention at \$4.10 per 100 lb., and large dealers were not inclined to quote below this figure at any time during the week. Quotations were generally heard at \$4.10@4.15 per 100 lb. for standard brand goods. *Spot caustic potash* has continued quite active all week, with sales reported up to 6c. per lb. for the imported 88-92 per cent. Large dealers are asking 6@6½c. for this product and it is very doubtful if shipment material can be placed below 6c. in any direction. Offerings on spot were not heavy, as most of the imported shipments have been practically sold upon arrival. The firm tendency that has been so prevalent in the *prussiate of soda* market has not let up and sales have been made at 14½@14¾c. per lb., with some sellers asking the outside figure in the late trading. Spot material is very scarce and the tone all around seems to be for higher prices.

Shipments are quoted firm at 14¼@14½c. per lb. Consumers are purchasing light *soda ash* in single bags at \$2.10@2.15 per 100 lb. Sales of barrels are reported at \$2.45@2.50 per 100 lb. Offerings were not heavy and numerous orders were booked for less than carload lots. Prices on *camphor* have been advanced by American refiners and the market closed in a very firm condition with buyers showing an increased interest. At the close prices were heard at 85@90c. per lb. Prices on *carbonate of copper* are quoted higher in some first-hand quarters, where sales are reported at 22c. per lb. In other directions a shade under this price can be done, but the tone of the market is decidedly stronger. *Spot formaldehyde* has been offered in the open market down to 11c. per lb. by second hands. The general range is from 11@12c. per lb. depending upon the quantity and seller. This product has not met with any active interest and first-hand competition has become keener for the small passing business. Prices on *oxalic acid* became somewhat firmer during the latter part of the week after a period of severe competition which brought the market down to 13c. per lb., the lowest figure recorded in the past few years. This price was still named by manufacturers at the close f.o.b. works, but spot material was quoted at 15c. per lb. Buyers were very cautious in buying quantities owing to the unsettled conditions for this product. Manufacturers of domestic *sulphide of soda* are meeting competition with the imported material and offer the 60-62 per cent, fused, at 4¾c. per lb. in carload quantities. The broken variety is quoted at 5c. per lb. in round lots and 5½c. in smaller portions. Crystals continue scarce, with 3½c. per lb. quoted for domestic material.

COAL-TAR PRODUCTS

There has been a substantial improvement noted in the entire list of coal-tar products during the past week and leading producers reported a more active demand than at any time this year. Consumers in many cases are requesting that some of their forward shipments be anticipated. Intermediate producers are more cheerful and feel that after a long depression of the most severe nature business is finally beginning in earnest. There were reports that orders were received from sources that were entirely out of the buying market for the past year. The active movement brought out the fact that spot material in resale hands is extremely low and that most of these products have been lying around for some time and are of an inferior quality. Prices in general have not changed to any marked extent and are not closely adhered to on firm business. The dye-stuff field has witnessed the greatest gain in the coal-tar products industry, as the textile business has recovered much of its lost ground. Business was particularly good in dimethylaniline, para phenylenediamine and phenol. Some resale *benzene* sold at 38@40c. per gal., but consumers found it extremely difficult to obtain any round quantities at this level. Refiners are turning down all offers for immediate business and are quoting only future shipments.

The St. Louis Market

ST. LOUIS, Mo., Oct. 27, 1921.

Trading in the chemical and drug markets for some time past has shown a consistent gain and during the past week a tremendous increase has been noticed, but it is the general opinion that the major part of this increase is only artificial, due to the present railroad situation. However, it is apparent that buyers are anticipating their requirements for a longer period than heretofore but nevertheless proceeding cautiously. The general trend of the market is very firm and weak holders are practically eliminated. The market as a whole is assuming a more normal and firmer position.

The market on *caustic soda* has not changed and is still moving normally at the prevailing price of \$4 per 100 lb., basis 73 to 75 per cent solid, f.o.b. point of production. The *soda ash* market remains slow with price unchanged from last week. *Bicarbonate* and *sal soda* have not changed.

Acetphenetidin is commanding a better position since most of the second-hand lots on the market have been cleared away. *Ammonia water*, 26 deg., is one of the stable articles and moves through regular channels throughout the year. The heavy demand for *ammonium sulphate, pure granular*, which was reported in our last letter continues at the present time. *Bismuth salts* continue to move in an unusually large quantity and are in greater demand. *Bromides* are showing some increase. *Caffeine* is on the road to recovery in spite of the fact that competition is still very keen. *Carbon bisulphide* is moving in a large way. *Ether* is increasing in inquiries and demand. *Glycerine* is in good demand at 14c., in 500-lb. drums. The *copperas* market continues along routine lines with no change in price. *Glycerophosphates* are on a better movement. A regular trade in *hypo* continues. Jobbers should bear in mind that the season for *creosotes* and *guaiacols* is approaching and should be prepared to meet the demand by carrying good stocks. The *iodides* are moving beyond manufacturers' expectations and orders of large volume are being placed. *Phenolphthalein* demand is above normal. *Saccharine* continues to move in a moderate way. *Salicylates* have improved considerably and, this being a seasonable article, buyers should not hesitate to order liberal quantities. Sales of fairly large proportions have been reported on *sodium benzoate*, although the season for this article is virtually over. *Strychnine salts* were reduced by manufacturers, *alkaloid* now being quoted at \$1.45 for crystals and \$1.35 for powdered and the *sulphate*, crystals and powdered, at \$1.15.

Manufacturers of heavy mineral acids report a general increase in activities and are very optimistic regarding the future. *Citric acid* demand is normal. *Acid tartaric* and *cream of tartar* are rather slow. Factors report a good increase in inquiries and demand for *pyrogallie acid*.

Castor oil is in strong demand with a price of 12½c., showing an increase of ½c. over previous report. *Linseed oil* suffered a drop during the preceding days, going as low as 68c., basis raw oil ex-warehouse. The demand is for spot and in small quantities. *Turpentine* remains steady at 79c. in single barrels and 75c. in 5-bbl. lots ex-warehouse.

Lithopone remains firm at 6½c., in less than carlots, and 6c. in carlots, with market getting stronger. Shipments have been good during the last ten days owing to the attempt of users trying to provide against the pending labor trouble. The market on *floatated barytes* has not changed, price \$23 per ton. The demand for this item shows an increase due to the pending railroad strike.

The Iron and Steel Market

PITTSBURGH, Oct. 28, 1921.

The United States Steel Corporation has taken the lead, promptly followed by independents, in reducing prices of standard section rails from \$45 per gross ton for bessemer rails and \$47 for open-hearth to \$40 for either description. About 1,500,000 tons of rails had been contracted for by the steam railroads for 1921 delivery, and about 1,000,000 tons had been taken out, the prospect being that the balance would be carried over to 1922. A reduction was in order for one time or another, as the old prices were those of the Industrial Board schedule of March 21, 1919, and all other steel products are now much below that schedule.

In most finished steel lines a slight tapering off in demand

is noticed in the past week, but a distinct exception is tubular goods, which show improved demand as to both oil country goods and standard pipe. In most trade circles there is a disposition to account for the change, after a period of three months of rather steadily increasing demand, on the ground that buyers are waiting for lower cost steel in connection with prospective freight rate reductions, which would lower the cost of steel and presumably the price, at the same time reducing the freight on the steel, paid by the buyer. The difficulty in accepting this explanation is that buying of steel products has been described right along as being of the hand-to-mouth character, and as rate reductions are unlikely to occur before about Jan. 1, if even on that date, it is difficult to see how there could be much postponement of buying such as would otherwise be in process. Perhaps a more natural explanation would be that steel demand has now recovered from its extreme depression, due to the necessity of liquidating stocks, and is now in normal relation to the character and volume of business the country is transacting, while the usual year-end dullness in the steel market is beginning to show itself.

STEEL PRICES

There have been no really important changes in finished steel prices for several weeks. There has been a sort of backing and filling in various branches of the trade, which in the general average has indicated no decided change toward softness or firmness. Tubular goods prices were formally reduced by the lists of Sept. 16, and these prices are now being shaded somewhat. Wire products were advanced Sept. 12, while the advance is not holding in all cases. Sheets were advanced \$5 a ton in September. The advance is holding in black and galvanized, but not in blue annealed. A second advance, \$5 a ton, has been announced by the majority of independents, but it is not actually effective, and the tone of the market is perhaps not as good as if the advance had not been attempted. Bars in small lots seem to be a shade firmer, but not in large lots. Shapes are reported firmer and plates weaker.

With the steel market in this somewhat unstable condition, with possibilities of demand being somewhat less active in the next few weeks, with freight rate reductions in near-by prospect, and with the showing that at present prices and wage rates and an operation at one-third of capacity, the Steel Corporation in September had earnings of \$15 a ton, against earnings averaging \$10 a ton in 1912 and 1913 with an operation of 88 to 90 per cent, the balance of probability is plainly that steel prices will tend to sag in the next few weeks rather than advance.

MILL OPERATIONS

Production of steel ingots appears to be at a rate nearer 40 per cent than 35 per cent of capacity, against an average of about 32 per cent in September and a dip under 20 per cent at the middle of July. Operation at rail, plate, shape and bar mills are under a 35 per cent rate on the whole, while the lighter products show a better operation, tin mills going at about 50 per cent, sheet mills at 65 to 85 per cent and pipe mills at 50 to 80 per cent.

PIG IRON AND COKE

Extreme dullness continues in the pig-iron markets and prices are not overly firm. It is improbable that prices can avoid yielding when coal, coke and limestone freight rates are reduced. The recent reduction in iron ore freight rates has not been reflected, as the furnaces had large piles of ore already and were anxious to liquidate, irrespective of the precise time of the freight rate reduction, which would affect fresh supplies. The market remains quotable, although now largely nominal, at \$20 for bessemer, \$19.25 to \$20 for basic and \$21 for foundry, f.o.b. valley furnaces.

Connellsville coke shows a slightly easier tone, prices remaining at approximately the cost of production. The balance is slightly against the coke operators, as they have been showing slightly more avidity in resuming operations than have the blast furnaces. The market is quotable as follows: Spot furnace, \$3.25 to \$3.50; contract furnace, \$3.40 to \$3.50; spot foundry, \$4.25 to \$4.75, per net ton at ovens.

Anthracene, 80% in drums (100 lb.)..... lb.	.75 — 1.00	.75 — 1.00
Benzaldehyde U.S.P..... lb.	1.35 — 1.45	1.35 — 1.45
Benzidine, base..... lb.	.90 — 1.00	.90 — 1.00
Benzidine sulphate..... lb.	.75 — .85	.75 — .85
Benzoic acid, U.S.P..... lb.	.60 — .65	.60 — .65
Benzoate of soda, U.S.P..... lb.	.52 — .55	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 — .32	.27 — .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 — .28	.25 — .28
Benzyl chloride, 95-97%, refined..... lb.	.25 — .27	.25 — .27
Benzyl chloride, tech..... lb.	.20 — .23	.20 — .23
Beta-naphthol benzoate..... lb.	3.50 — 4.00	3.50 — 4.00
Beta-naphthol, sublimed..... lb.	.70 — .75	.70 — .75
Beta-naphthol, tech..... lb.	.31 — .34	.31 — .34
Beta-naphthylamine, sublimed..... lb.	1.75 — 1.85	1.75 — 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 — .17	.16 — .17
Ortho-cresol, in drums (100 lb.)..... lb.	.25 — .27	.25 — .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 — .80	.70 — .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 — .70	.65 — .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 — .50	.45 — .50
Dichlorobenzene..... lb.	.06 — .09	.06 — .09
Diethylaniline..... lb.	1.10 — 1.20	1.10 — 1.20
Dimethylaniline..... lb.	.60 — .65	.60 — .65
Dinitrobenzene..... lb.	.23 — .27	.23 — .27
Dinitrochlorobenzene..... lb.	.20 — .25	.20 — .25
Dinitronaphthalene..... lb.	.30 — .35	.30 — .35
Dinitrophenol..... lb.	.35 — .40	.35 — .40
Dinitrotoluene..... lb.	.25 — .30	.25 — .30
Dip oil, 25%, car lots, in drums..... gal.	.30 — .35	.30 — .35
Diphenylamine..... lb.	.60 — .70	.60 — .70
H-acid..... lb.	1.05 — 1.15	1.05 — 1.15
Meta-phenylenediamine..... lb.	1.15 — 1.20	1.15 — 1.20
Monoethylaniline..... lb.	.12 — .14	.12 — .14
Monoethylaniline..... lb.	1.65 — 1.70	1.65 — 1.70
Naphthalene crushed, in bbls..... lb.	.06 — .08	.06 — .08
Naphthalene, flake..... lb.	.06 — .08	.06 — .08
Naphthalene, balls..... lb.	.08 — .09	.08 — .09
Naphthionic acid, crude..... lb.	.70 — .75	.70 — .75
Nitrobenzene..... lb.	.12 — .15	.12 — .15
Nitro-naphthalene..... lb.	.30 — .35	.30 — .35
Nitro-toluene..... lb.	.15 — .17	.15 — .17
Ortho-amidophenol..... lb.	3.00 — 3.10	3.00 — 3.10
Ortho-dichlor-benzene..... lb.	.15 — .20	.15 — .20
Ortho-nitro-phenol..... lb.	.75 — .80	.75 — .80
Ortho-nitro-toluene..... lb.	.15 — .20	.15 — .20
Ortho-toluidine..... lb.	.20 — .25	.20 — .25
Para-amidophenol, base..... lb.	1.40 — 1.45	1.40 — 1.45
Para-amidophenol, HCl..... lb.	1.70 — 1.80	1.70 — 1.80
Para-dichlorobenzene..... lb.	.12 — .15	.12 — .15
Paranitroaniline..... lb.	.77 — .80	.77 — .80
Para-nitrotoluene..... lb.	.80 — .85	.80 — .85
Para-phenylenediamine..... lb.	1.70 — 1.75	1.70 — 1.75
Para-toluidine..... lb.	1.25 — 1.40	1.25 — 1.40
Phthalic anhydride..... lb.	.40 — .50	.40 — .50

Phenol, U. S. P., drums..... lb.	.09 — .12	.09 — .12
Pyridine..... gal.	2.00 — 3.50	2.00 — 3.50
Resorcinol, technical..... lb.	1.50 — 1.60	1.50 — 1.60
Resorcinol, pure..... lb.	2.00 — 2.25	2.00 — 2.25
Salicylic acid, tech., in bbls..... lb.	.18 — .20	.18 — .20
Salicylic acid, U. S. P..... lb.	.19 — .22	.19 — .22
Salol..... lb.	.60 — .70	.60 — .70
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 — .28	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 — .16	.14 — .16
Sulphanilic acid, crude..... lb.	.27 — .30	.27 — .30
Tolidine..... lb.	1.30 — 1.35	1.30 — 1.35
Toluidine, mixed..... lb.	.43 — .45	.43 — .45
Toluene, in tank cars..... gal.	.25 — .28	.25 — .28
Toluene, in drums..... gal.	.28 — .31	.28 — .31
Xylidines, drums, 100 gal..... lb.	.40 — .45	.40 — .45
Xylene, pure, in drums..... gal.	.40 — .45	.40 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .30	.30 — .30

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.19 — \$0.20	\$0.19 — \$0.20
Beeswax, refined, dark..... lb.	.24 — .25	.24 — .25
Beeswax, refined, light..... lb.	.28 — .30	.28 — .30
Beeswax, white pure..... lb.	.36 — .40	.36 — .40
Candelilla wax..... lb.	.24 — .25	.24 — .25
Carnauba, No. 1..... lb.	.46 — .47	.46 — .47
Carnauba, No. 2, North Country..... lb.	.24 — .24	.24 — .24
Carnauba, No. 3, North Country..... lb.	.14 — .15	.14 — .15
Japan..... lb.	.21 — .22	.21 — .22
Montan, crude..... lb.	.04 — .05	.04 — .05
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03 — .03	.03 — .03
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 — .02	.02 — .02
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 — .03	.03 — .03
Paraffine waxes, refined, 125 m.p..... lb.	.03 — .03	.03 — .03
Paraffine waxes, refined, 128-130 m.p..... lb.	.03 — .03	.03 — .03
Paraffine waxes, refined, 133-135 m.p..... lb.	.04 — .04	.04 — .04
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 — .05	.05 — .05
Stearic acid, single pressed..... lb.	.09 — .09	.09 — .09
Stearic acid, double pressed..... lb.	.10 — .10	.10 — .10
Stearic acid, triple pressed..... lb.	.11 — .11	.11 — .11

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.45 — 5.50	\$5.45 — 5.50
Rosin E-I..... 280 lb.	5.55 — 5.75	5.55 — 5.75
Rosin K-N..... 280 lb.	6.10 — 6.75	6.10 — 6.75
Rosin W. G.-W. W..... 280 lb.	7.00 — 7.25	7.00 — 7.25
Wood rosin, bbl..... 280 lb.	6.25 — 6.25	6.25 — 6.25
Spirits of turpentine..... gal.	.82 — .82	.82 — .82
Wood turpentine, steam dist..... gal.	.80 — .80	.80 — .80
Wood turpentine, dest. dist..... gal.	.78 — .78	.78 — .78
Pine tar pitch, bbl..... 200 lb.	6.50 — 6.50	6.50 — 6.50
Tar, kiln burned, bbl. (500 lb.)..... bbl.	10.00 — 10.00	10.00 — 10.00
Retort tar, bbl..... 500 lb.	10.00 — 10.00	10.00 — 10.00
Rosin oil, first run..... gal.	.35 — .35	.35 — .35
Rosin oil, second run..... gal.	.37 — .37	.37 — .37
Rosin oil, third run..... gal.	.44 — .44	.44 — .44
Pine oil, steam dist., sp.gr., 0.930-0.940..... gal.	1.90 — 1.90	1.90 — 1.90
Pine oil, pure, dest. dist..... gal.	1.50 — 1.50	1.50 — 1.50
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 — .46	.46 — .46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 — .35	.35 — .35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 — .75	.75 — .75
Pine tar, ref., thin, sp.gr., 1.080-1.060..... gal.	.35 — .35	.35 — .35
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25 — 1.25	1.25 — 1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 — .35	.35 — .35
Pinewood creosote, ref..... gal.	.52 — .52	.52 — .52

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 — .37	\$0.37 — .37
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 — .35	.35 — .35
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 — .34	.34 — .34
V. M. and P. naphtha, steel bbls (85 lb.)..... gal.	.23 — .23	.23 — .23

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.70 — 3.00	\$2.70 — 3.00
Blood, dried, f.o.b., N. Y..... unit	4.00 — 4.00	4.00 — 4.00
Bone, 3 and 50, ground, raw..... ton	30.00 — 32.00	30.00 — 32.00
Cyanamide, f.o.b. works..... unit	4.50 — 4.50	4.50 — 4.50
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 — 3.00	2.90 — 3.00
Nitrate soda..... 100 lb.	2.35 — 2.45	2.35 — 2.45
Tankage, high grade, f.o.b. Chicago..... unit	3.00 — 3.10	3.00 — 3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	4.50 — 6.50	4.50 — 6.50
Tennessee, 78-80 p.c..... ton	8.00 — 9.00	8.00 — 9.00
Potassium muriate, 80 p.c..... ton	37.50 — 40.00	37.50 — 40.00
Potassium sulphate..... unit	1.15 — 1.20	1.15 — 1.20

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 — .21	\$0.21 — .21
Upriver coarse..... lb.	.11 — .12	.11 — .12
Upriver caucho ball..... lb.	.11 — .12	.11 — .12
Plantation—First latex crepe..... lb.	.15 — .15	.15 — .15
Ribbed smoked sheets..... lb.	.15 — .15	.15 — .15
Brown crepe, thin, clean..... lb.	.15 — .15	.15 — .15
Amber crepe No. 1..... lb.	.17 — .17	.17 — .17

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 — \$0.10	\$0.10 — \$0.10
Castor oil, AA, in bbls..... lb.	.11 — .12	.11 — .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.13 — .13	.13 — .13
Cocanut oil, Ceylon grade, in bbls..... lb.	.09 — .09	.09 — .09
Cocanut oil, Cochin grade, in bbls..... lb.	.10 — .10	.10 — .10
Corn oil, crude, in bbls..... lb.	.10 — .10	.10 — .10
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07 — .07	.07 — .07
Cottonseed oil, summer yellow..... lb.	.09 — .09	.09 — .09
Cottonseed oil, winter yellow..... lb.	.09 — .10	.09 — .10

Linseed oil, raw, ear lots (domestic).....	gal.	67	—	68
Linseed oil, raw, tank cars (domestic).....	gal.	62	—	63
Linseed oil, in 5-bbl lots (domestic).....	gal.	70	—	71
Olive oil, Denatured.....	gal.	\$1.15	—	\$1.20
Palm, Lagos.....	lb.	.07	—	.07½
Palm, Niger.....	lb.	.06½	—	.06¾
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.08½
Peanut oil, refined, in bbls.....	lb.	.11½	—	.11¾
Rapeseed oil, refined in bbls.....	gal.	.85	—	.87
Rapeseed oil, blown, in bbls.....	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.09	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.07½	—	

FISH

Light pressed menhaden.....	gal.	\$0.40	—	
Yellow bleached menhaden.....	gal.	.42	—	
White bleached menhaden.....	gal.	.44	—	
Blown menhaden.....	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	20.00	—	24.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04	—	.04½
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.07	—	.10
Chalk, Precipitated, domestic, extra light.....	lb.	.04½	—	.05
Chalk, Precipitated, domestic, light.....	lb.	.04	—	.04½
Chalk, Precipitated, domestic, heavy.....	lb.	.03½	—	.04
Chalk, Precipitated, English, extra light.....	lb.	.04½	—	.05
Chalk, Precipitated, English, light.....	lb.	.04½	—	.05
Chalk, Precipitated, English, dense.....	lb.	.04	—	.04½
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	13.00	—	20.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.06	—	.07
Graphite, Ceylon chip.....	lb.	.04½	—	.05
Graphite, high grade amorphous crude.....	lb.	.00¾	—	.02½
Kieselguhr, f.o.b. mines, Cal.....	per ton	40.00	—	
Kieselguhr, f.o.b. N.Y.....	per ton	61.00	—	
Magnesite, calcined.....	per ton	66.00	—	70.00
Pumice stone, imported.....	lb.	.03	—	.40
Pumice stone, domestic, lump.....	lb.	.05	—	.05½
Pumice stone, domestic, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.68	—	.70
Shellac, orange superfine.....	lb.	.80	—	.82
Shellac, A. C. garnet.....	lb.	.58	—	.60
Shellac, T. N.....	lb.	.68	—	.70
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	7.50	—	11.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	25.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$50.00	—	
Carborundum refractory brick, 9-in. { less than carlot	1,000	1250.00	—	
Chrome brick, f.o.b. Eastern shipping points.....	net ton	52- 55	—	
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30- 32	—	
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	33- 35	—	
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	35- 40	—	
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30- 35	—	
Magnesite brick, 9-in. straight.....	net ton	65- 70	—	
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77	—	
Magnesite brick, soaps and splits.....	net ton	98	—	
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	40- 42	—	
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	42- 45	—	
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35- 38	—	

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferrocchrome per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.11	—	
Ferrocchrome per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.11	—	.12
Ferromanganese, 76-80% Mn, domestic.....	gross ton	60.00	—	63.00
Ferromanganese, 76-80% Mn, English & German.....	gross ton	59.00	—	60.00
Spiegelisen, 18-22% Mn.....	gross ton	25.00	—	27.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.25	—	
Ferrosilicon, 10-15%.....	gross ton	38.00	—	40.00
Ferrosilicon, 50%.....	gross ton	60.00	—	65.00
Ferrosilicon, 75%.....	gross ton	130.00	—	135.00
Ferrotungsten, 70-80%, per lb. of contained W.....	lb.	.40	—	.45
Ferrouanium, 35-50% of U, per lb. of U content.....	lb.	6.00	—	
Ferrovandium, 30-40% per lb. of contained V.....	lb.	4.25	—	4.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content.....	net ton	\$8.00	—	\$10.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	ton	24.00	—	26.00
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard.....	ton	24.00	—	26.00
Coke, foundry, f.o.b. ovens.....	net ton	4.25	—	4.50
Coke, furnace, f.o.b. ovens.....	net ton	3.25	—	3.50
Coke, petroleum, refinery, Atlantic seaboard.....	net ton	12.00	—	13.00
Fluorspar, gravel, f.o.b. mines, New Mexico.....	net ton	15.00	—	
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	20.00	—	22.00
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01½	—	.01¾
Manganese ore, 50% Mn, c.i.f. Atlantic seaport.....	unit	.20	—	.21
Manganese ore, chemical (MnO ₂).....	net ton	50.00	—	55.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.....	lb.	.55	—	.60
Monazite, per unit of ThO ₂ , c.i.f. Atlantic seaport.....	unit	30.00	—	
Pyrites, Spanish, fines, c.i.f. Atlantic seaport.....	unit	.12	—	.12

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

TUSCALOOSA—Members of the industrial committee of the local Chamber of Commerce are perfecting plans for the establishment of a local paper mill, to specialize in the manufacture of bond, kraft and other papers.

California

SAN FRANCISCO—Technion, Inc., manufacturer of composition of tiling, wainscoting, etc., has established a new plant at 524 Gough St., and plans for extensive operations. Alexander R. Balm is president, and J. W. Rowell, vice-president and production manager.

Georgia

COLUMBUS—The Southern Cotton Oil, Ninth Ave., is said to be planning for the rebuilding of its plant, recently partly destroyed by fire.

Illinois

CHICAGO—The American Tar Products Co., 208 South La Salle St., has commenced the erection of its proposed new local plant, to be equipped for the production of tar and tar byproducts.

Louisiana

ABBEVILLE—The Peoples' Sugar Refinery, Rose Hill, near Abbeville, is planning for the rebuilding of its local sugar mill, destroyed by fire, Oct. 13, with loss estimated at about \$300,000, including machinery.

Maryland

BALTIMORE—The Chesapeake Paper Board Co., Key Highway and Baltimore & Ohio R.R., will soon commence the enlargement of its plant to provide approximately double the present output, or about 100,000 lb. of material every 24 hours. The machinery installation is estimated to cost in excess of \$50,000. An extension will be constructed to the power house. J. S. Smith is president.

BALTIMORE—The American Sugar Refining Co. has filed plans for the erection of another building at its new plant now in course of erection at Woodall and Clements Sts. It will be 1-story, 55 x 107 ft. Stone & Webster, Inc., 120 Broadway, New York, has the building contract.

BALTIMORE—The Patuxent Clay Products Co., 206 Water St., recently incorporated with a capital of \$1,000,000, is having plans prepared for the erection of a new local plant to cost about \$150,000, for the manufacture of hollow tile and other burned clay products. The company is headed by Herbert W. Holmes and Harry Hanna.

Massachusetts

LEOMINSTER—The Viscaloide Co., manufacturer of celluloid products, has awarded a contract to Wiley & Foss, Central St., Fitchburg, Mass., for the construction of a 3-story plant addition on Lancaster St., 40 x 50 ft. A. S. Paton is president.

SALEM—The Atlantic Refining Co., 3144 Passyunk Ave., Philadelphia, Pa., manufacturer of oil products, is planning for the erection of a new local plant on Jeffers Ave. New England headquarters are at 248 Boylston St.

Michigan

CADILLAC—R. J. Teetor, Muskegon, Mich., is completing plans for the erection of a new 1-story and basement foundry, 75 x 100 ft., at Cadillac. Frank D. Chase, Inc., 645 Michigan Ave., Chicago, Ill., is architect and engineer.

ANN ARBOR—The University of Michigan, S. W. Smith, secretary, University Hall Bldg., has preliminary plans under way for the erection of a new chemical laboratory at the institution, estimated to cost about \$75,000.

Missouri

ST. LOUIS—The République Photographie Corp., Kansas City, Mo., has acquired property totaling about 6 acres at St. Louis, to be used as a site for the erection of a new plant for sensitized photographic paper manufacture. Preliminary plans are under way. E. B. Fish is president.

ST. LOUIS—The St. Louis Lead & Oil Works, International Life Bldg., will break ground at once for the erection of a new power house at its plant on Manchester St.

New Jersey

CAMDEN—Fire, Oct. 19, destroyed a portion of the plant of the Camden Copper Works, Second and Royden Sts., with loss estimated at about \$11,000.

NEWARK—The Celluloid Co., 290 Ferry St., manufacturer of celluloid products, has awarded a contract to Enstice Bros., 40 Clinton St., for the erection of a new 1-story and basement building, 73 x 240 ft., at Westcott and Niagara Sts., estimated to cost about \$200,000.

JERSEY CITY—Fire, Oct. 15, destroyed a portion of the plant of the C. A. Woolse Paint & Color Co., 500 Grand St. An official estimate of the loss has not been made.

TRENTON—Fire, Oct. 21, destroyed a portion of the plant of the Enterprise Rubber Co., Enterprise Ave., manufacturer of rubber products, with loss estimated at about \$25,000. John McCue is head.

New York

NIAGARA FALLS—The American Motorists' Refining Co., has construction under way on a new oil refinery on a 30-acre tract of property recently acquired in the northern section of the city.

ROCHESTER—The Pennsylvania Glass Sand Co., Lewiston, Me., is reported to be planning for the immediate erection of a new local mill, to be equipped for grinding feldspar, etc., estimated to cost about \$45,000, to be 1-story, 50 x 130 ft.

BUFFALO—The Standard Mirror Co., 155 Harrison St., has plans under way for the erection of a new 1-story building at its plant, 60 x 120 ft. Bids will be asked at once. Colson & Hudson, Dun Bldg., are architects.

North Carolina

SALISBURY—The American Foundry Co. is completing plans for the erection of a new 1-story foundry, 60 x 120 ft., for the production of iron and other metal castings. Thomas G. Shelton is manager.

MICAVILLE—The Carolina Feldspar Co., Box 1025, Asheville, N. C., is planning for extensive developments and operations at its properties in the vicinity of Micaville, to include the grinding and pulverizing spar and kindred products. F. Frazier Glenn is president and general manager, address noted.

BURLINGTON—The Chamber of Commerce is developing plans for the establishment of a new local plant for the manufacture of terra cotta specialties, drain tile and other burned clay products. J. V. Mann is secretary.

Ohio

BARBERTON—The receivers for the Portage Rubber Co. have offered the plant and property to F. A. Seiberling, former head of the Goodyear Tire & Rubber Co. and now president of the Lehigh Tire & Rubber Co., New Castle, Pa., for a consideration of \$1,000,000, or \$250,000 in excess of the amount Mr. Seiberling has tendered for the works. If the sale is consummated, the plant will be operated in conjunction with the New Castle works.

YOUNGSTOWN—The Paul J. Kalman Co., 22 West Munroe St., Chicago, Ill., manufacturer of steel products, is planning for the early erection of a new steel fabricating plant, 400 x 420 ft., at Youngstown, estimated to cost close to \$200,000 with equipment.

Pennsylvania

KITTANING—The Templeton Limestone Co., with plant at Templeton, near Kittanning, has construction under way on the

rebuilding of its crusher building and power house, 30 x 60 ft., and 25 x 25 ft., respectively, recently destroyed by fire. The work is estimated to cost about \$50,000. W. L. Snyder is superintendent.

KANE—Fire, Oct. 18, destroyed a building of the Nansen Chemical Co., Nansen, near Kane, with loss estimated at about \$25,000.

PHILADELPHIA—The Pennsylvania Sugar Co., North Penn St., has acquired the property at 1015-21 North Penn St., adjoining its works, from the J. W. Paxson Co., for a consideration said to be \$145,000. The site is improved with a 3-story factory and other buildings, and will be used by the new owner in connection with its plant.

WILLIAMSPORT, PA.—C. A. Reed & Co., Willow and Laurel Sts., manufacturer of paper products, has awarded a contract to Charles W. Feil & Co., South and Willow Sts., for the erection of its proposed new 4-story plant, 70 x 100 ft., estimated to cost \$100,000.

PHILADELPHIA—The Philadelphia Paper Mfg. Co., Mixon St., Manayunk, has filed plans for the erection of a new building at its plant 100 x 180 ft., estimated to cost about \$30,000.

Tennessee

CHATTANOOGA—The Ocoee Copper Co., 1135 Volunteer Life Bldg., has plans under way for the erection of a new plant at Ducktown, near Chattanooga, estimated to cost about \$200,000. J. I. Carter is president. L. R. Hope, Ducktown, is engineer.

MEMPHIS—G. N. Shepardson is considering plans for the rebuilding of his local potash manufacturing plant, recently damaged by fire with loss of about \$23,000.

CHATTANOOGA—The Cities Brick Co., Curtain Pole Road, has preliminary plans under way for the erection of an addition to its plant.

Texas

BEAUMONT—The Magnolia Petroleum Co., Dallas, Tex., is planning for the rebuilding of the portion of its gasoline plant recently destroyed by fire with loss reported in excess of \$300,000.

BRECKENRIDGE—The laboratory building and other structures at the plant of the Mystic Gasoline Co., were destroyed by fire, Oct. 4, with loss estimated at about \$14,000.

West Virginia

BELLE—The Belle Alkali Co. has awarded a contract to the Korns-Thomas Contracting Co., First National Bank Bldg., Huntington, W. Va., for the erection of additions in its plant, including improvements and alterations in the present works, estimated to cost about \$300,000. D. W. Stubblefield is manager.

SUTTON—The Sutton Chemical Co. has acquired a large tract of property, totaling about 5,000 acres in the vicinity of Wolf and Stoney Creeks, to be used for certain raw material supply for the local plant.

PRINCETON—The Princeton Brick Co. has plans under way for extensions and improvements in its plant. Additional machinery will be installed.

STAR CITY—The new plant of the Star Glass Co., 93 Washington St., Morgantown, W. Va., to be erected at Star City, will total about 75,000 sq. ft. of manufacturing area, and is estimated to cost about \$200,000. Construction will be commenced at once. H. J. Wagoner is secretary and treasurer.

Capital Increases, Etc.

THE UNITED STATES TURPENTINE & ROSIN Co., Mobile, Ala., has filed notice of increase in capital from \$3,000,000 to \$6,000,000.

THE STANWOOD RUBBER Co., Newark Ave., Elizabeth, N. J., has been taken over by a reorganization committee and receivership, operative for about a year past, has been terminated. The new company proposes to issue bonds for \$175,000 and stock for \$651,000, and will operate the local plant. A consideration of \$360,000 was given for the property.

THE MARTIN LEATHER Co., Fifth and Spruce Sts., Wilmington, Del., has filed notice of increase in capital from \$700,000 to \$1,500,000.

A stockholders' committee is perfecting plans for the reorganization of the **BUTTERWORTH-JUDSON CORP., Doremus Ave., Newark, N. J.,** manufacturer of chemicals, dyes, etc. The committee is composed of Chellis A. Austin, chairman; William A. Bradford, and Thomas L. Chadbourne.

New Companies

THE IVA-LITE CORP., Boston, Mass., has been incorporated with a capital of \$250,000, to manufacture glass products of various kinds. Robert T. Russell is president; and M. S. MacDonald, 175 Cypress St., Newton, Mass., treasurer.

NOEPEL & BLAIR, INC., Boonton, N. J., has been incorporated with a capital of \$25,000, to manufacture leather products. The incorporators are Charles W. Blair, I. J. and Jacob E. Noepel, 65 Harrison St., Boonton.

THE GWYNED CLAY PRODUCTS CO., Wilmington, Del., has been incorporated under state laws with a capital of \$125,000, to manufacture hollow tile, firebrick and other burned clay products. The company is represented by the Delaware Charter Co., 904 Market St., Wilmington.

THE BORG CORPORATION, New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture shellac, glue and kindred products. The incorporators are F. C. Leubuscher, J. W. Suling and J. C. Skinner. The company is represented by Leubuscher & Suling, 258 Broadway, New York.

THE MOTOR CITY SOAP CO., Detroit, Mich., has been organized under state laws to manufacture soaps and affiliated products. The incorporators are James L. and F. Cowan, and Ira Snyder, 5715 Third Ave., Detroit.

THE CHICAGO DRUG & CHEMICAL MFG. CO., 2201 West Roosevelt Road, Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts, drugs, etc. The incorporators are David Rish, Max Karno and Benjamin Michelson.

THE HUDSON VALLEY PORTLAND CEMENT CO., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture cement. The incorporators are H. W. Davey, M. S. Reeve and E. F. Mack, Jr. The company is represented by Hyman Dominitz, 152 West 42d St.

THE MOUNTAIN LIME CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000, to manufacture lime and affiliated products. The incorporators are V. C. Hickson, W. J. Little and T. P. Lamb. The company is represented by Randal, Bartlett & White, 605 California Bldg.

THE M. & S. SHELLAC CO., Newton, Mass., has been incorporated with a capital of \$3,600, to manufacture shellac, varnish and kindred products. Thomas J. Mitchell is president; and Isidor Slotwick, 87 Congress St., Chelsea, Mass., treasurer.

THE SATISFACTO PRODUCTS CO., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are O. W. Sample, H. Gerbitz and T. J. Ward. The company is represented by M. A. Barney, 154 Nassau St., New York.

THE HARDMAN PRODUCTS CO., Caldwell, N. J., has been incorporated with a capital of \$50,000, to manufacture rubber products. The incorporators are J., Herbert V. and L. N. Hardman, 29 Elizabeth St., Caldwell.

THE MAXWELL PAINT CO., Philadelphia, Pa., has been incorporated with a capital of \$10,000, to manufacture paint, varnish, etc. H. C. Middletown, Jr., Moorestown, N. J., is treasurer.

THE DORADIAN OIL CO., El Dorado, Ark., has been incorporated with a capital of \$125,000, to manufacture petroleum products. The incorporators are F. N. Fisher, A. J. Falls and Benjamin R. Henderson, all of Memphis, Tenn.

THE TUCAN CLAY PRODUCTS CO., Chicago, Ill., has been incorporated with a capital of \$250,000, under Delaware laws, to manufacture clay products. The incorporators are C. W. Smith, J. N. Fulton and J. M. Fitzpatrick, Chicago. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE ASBESTOS PRODUCTS MFG. CO., Hoboken, N. J., has been incorporated with a capital of \$10,000, to manufacture asbestos goods of various kinds. The incorporators are William D. Crumpton, Frank Richl and Elwood J. Wilson, 1021 Grand St., Hoboken.

THE MAGNUS CHEMICAL CO., Brooklyn, N. Y., has been incorporated with a capital of \$90,000, to manufacture chemicals and chemical byproducts. The incorporators are W. M. and W. J. Campbell, and E. Magnuson. The company is represented by Henry Amerman, 233 Broadway, New York.

THE WYATT RUBBER CO., 233 East 22d St., Baltimore, Md., has been incorporated with a capital of \$50,000, to manufacture

rubber products. The incorporators are Charles M. Reckord and Francis J. Hamill.

THE A. B. HURST CO., Kendall, Fla., has been incorporated with a capital of \$25,000, to manufacture starch and affiliated products. A. B. Hurst, is president; W. T. Tomlinson, vice-president; and John B. Hurst, secretary, all of Kendall.

THE PINE TREE PULP CO., Gardiner, Me., has been incorporated with a capital of \$100,000, to manufacture paper-pulp and affiliated products. J. Harold Machette is president and treasurer. Robert K. Eaton, Gardiner, represents the company.

THE LAWLOR-McCORMICK CO., New Brunswick, N. J., has been incorporated with a capital of \$50,000, to manufacture coal-tar byproducts and affiliated specialties. The incorporators are Joseph J. Lawlor, William J. Lawlor and Clifford J. McCormick. The company is represented by Neilson & Hamilton, New Brunswick.

THE LIBERTY GLASS CO., Wilmington, Del., has been incorporated under state laws, with capital of \$200,000, to manufacture glass products. The company is represented by the Capital Trust Co., Dover, Del.

THE APEX COLOR CO., Providence, R. I., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture colors, dyes and kindred products. The incorporators are Herbert J. Humphres, and Clifton I. Munroe, Providence; and Ogden R. Lindsley, Central Falls, R. I.

THE WELLSTAN OIL CO., New York, N. Y., has been incorporated with a capital of \$200,000, to manufacture oil products. The incorporators are Charles Newburg, Anthony N. Roderink and Randolph S. Barrie, New York. The company is represented by the United States Corporation Co., 65 Cedar St.

THE EXCELSIOR LEATHER CO., New York, N. Y., has been incorporated with a capital of \$30,000, to manufacture leather products. The incorporators are W. and E. Fried, and E. Tucker. The company is represented by Abraham Karp, 350 Broadway.

KERR, WILSON & CO., INC., Roanoke, Va., has been incorporated with a capital of \$250,000, to manufacture tannin extracts for leather working, dye products, etc. George A. Kerr is president; Walter F. Wilson, vice-president; and J. Calvin Moss, secretary-treasurer, all of Lynchburg, Va.

THE AMERICAN COBALT PRODUCTS CO., Jersey City, N. J., has been incorporated with a capital of \$1,500,000, to manufacture cobalt compounds and affiliated products. The company is represented by the Corporation Trust Co., 15 Exchange Pl., Jersey City.

Manufacturers' Catalogs

THE K-B PULVERIZER CO., INC., New York, N. Y., has issued a folder on the Pulver-burner.

THE PIRON COAL DISTILLATION SYSTEMS, New York, N. Y., in Bulletin 1 illustrates and describes coke and gas oven byproduct plants and distillation recovery systems.

C. G. BUCHANAN CO., INC., New York, calls attention to Bulletin 13, on Type "C" Buchanan crushing rolls. On page 2 is given a brief history of the original and first introduction of rolls. This in itself would probably be of little interest to the average reader, but the data given on the large capacity and the comparatively small amount of power required to operate these early and imperfect machines must be of keen interest to any one who is not thoroughly familiar with the use or possibilities of rolls as a crushing device for medium fine crushing. This company has endeavored to make clear the limitations of rolls in regard to size of pieces that rolls can economically handle and the reduction that can be made in a single pass, and convenient tables and diagrams are given on pages 8 and 10. Simple tables of capacities are given on pages 12 and 13, enabling the users of rolls to determine quickly the size, speed and number of rolls to be used for accomplishing any given amount of work.

THE EAGLE-PICHER LEAD CO., Chicago, Ill., has issued an attractive booklet on Eagle-Picher Products. A "Lead Tree" chart is given showing the comprehensiveness of the company's operations; composition and use of white lead, blue lead, litharge, red lead and orange mineral, etc.; a list of metal products which find most general use in the lead-consuming industries; and specifications of lead pipes, traps, roof flanges and lead bottles and specialties.

New Publications

PROBLEMS FOR RESEARCH TRAINING. By Research Committee, H. A. Shoule, chairman. 30 pp. Sciencetech Club, Indianapolis, Ind.

This little pamphlet addressed to the members of the scientific and technical faculties of Indiana colleges and universities lists 175 different research problems awaiting solution in the fields of botany, chemistry, engineering and physics. These problems, for the most part, have been suggested by active professional men who are appreciative of the actual needs of the industries they represent.

OIL FLOW IN PIPE LINES. By R. S. Danforth. Ten charts and two pages of instructions. Published by King Knight Co., San Francisco, Cal. Price \$3.

A series of charts for use in solving oil-pumping problems have been prepared by the author using the formulas and method of computation explained in a previous bulletin, "Friction Pressure Loss in Oil Pipe Lines" published by the Kinney Manufacturing Co., of Boston, Mass.

THE AMERICAN ACADEMY OF ARTS AND SCIENCES has issued a booklet on "The Potential of the Thallium Electrode and the Free Energy of Formation of Thallous Iodide," by Grinnell Jones and Walter Cecil Schumb.

THE UNIVERSITY OF ILLINOIS has issued bulletins on "Investigation of Warm-Air Furnaces and Heating Systems," by A. C. Willard, A. P. Kratz and V. S. Day; "The Functions of the Engineering Experiment Station of the University of Illinois," by Charles Russ Richards, and "Some Conditions Affecting the Usefulness of Iron Oxide for City Gas Purification," by William A. Dunkley.

THE IOWA STATE COLLEGE has issued a bulletin on "Effects on Concrete of Immersion in Boiling Water and Oven Drying," by W. J. Schlick.

THE FEDERAL POWER COMMISSION has issued a booklet on Rules and Regulations as amended by Order No. 11 of June 6, 1921, governing the administration of the federal water power act, with copies of the act, of amendment thereto, and of orders Nos. 1 to 11 inclusive.

Coming Meetings and Events

ACADEMY OF POLITICAL SCIENCE will hold its forty-first annual meeting at the Hotel Astor, New York City, Nov. 4 and 5.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN IRON AND STEEL INSTITUTE will hold its twentieth general meeting at the Hotel Commodore, New York City, on Friday, Nov. 18.

INDUSTRIAL COST ASSOCIATION will hold its second national conference at Pittsburgh, Pa., Nov. 2-4, with headquarters at the William Penn Hotel.

INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA is holding its annual convention at the Waldorf-Astoria, New York, Nov. 1-5.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

Number 19

The Arms Conference And Chemical Warfare

CHEMICAL warfare is certain to come in for an exhaustive discussion at the Conference on the Limitation of Armament, which opens this week in Washington. It is admitted generally that the universal recognition of gas as a proper weapon would make it possible for armaments to be limited to a far greater extent than would be the case otherwise. Without discounting in any way its effectiveness as a weapon of offense, gas is coming to be regarded as one of the most potent of the weapons of defense.

An indication of the recognition of the importance of chemical warfare in any discussion of armaments is the selection of General AMOS A. FRIES, head of the Chemical Warfare Service of the Army, as a member of the technical staff of the American delegation. Further recognition of the chemical industry is had in the appointment of Dr. EDGAR F. SMITH, president of the American Chemical Society, as representative of the scientific and professional element, and of WILLIAM S. CULBERTSON, the Tariff Commissioner who has dealt principally with chemical tariff problems.

If an effort is made at the conference to prohibit the use of gas in warfare, it is believed it will be prompted by a desire to see the United States stripped of a weapon which she is in a position to use to greater advantage than any other country. The United States has ample supplies of all the raw materials used in chemical warfare. In this she has an advantage over any other country. With proper development in time of peace she would have industries equipped for immediate conversion to gas warfare purposes. In addition to these advantages, the United States is separated from possible powerful enemies by oceans. By the use of gas, our defense could be greatly strengthened. Even with gas in the infancy of its development, it is very generally recognized by military authorities that it makes the landing of troops from overseas so difficult that no attempt would be made to land them directly on our shores.

Another point, frequently lost sight of, is the fact that gas can be limited in its use against non-combatants to the same extent that other weapons of warfare are limited. The most frequently used argument against gas is that non-combatants suffer along with combatants. But we may point out that this applies to all weapons used in the recent war and does not constitute an argument against chemical warfare, since its possibilities of destruction can be confined to certain areas with almost the same exactness as would apply to other weapons. In that connection, however, it may be stated that military authorities do not expect great concern for civilian populations in future wars. The means of warfare have changed to such an extent that discrimination between combatants and non-combatants is growing increasingly difficult.

It is expected that the American delegation will advocate the retention of chemical warfare since the Congress of the United States has approved on several occasions the use of gas in warfare and has set up within the Army the most pretentious chemical warfare service in the world.

The Blight of Finance On Technical Enterprises

THE old-fashioned merchant is passing away. He used to be very much of a person. He ruled his affairs and his employees as well as his junior partners with patriarchal firmness; but he knew his business. He was likely to be a gentleman in what we call the American sense of the word—that is, he was polite in his mind and in his heart, rich in sympathy and gifted with understanding. Often, indeed, he was a man of distinguished culture and a person of taste. He took a reasonable pride in his high station, but still more seriously did he consider and live up to his obligations.

The old-fashioned manufacturer is a later creation, but he, too, is passing. He knew the business end of his industry and he had an understanding of its technology, so far as the old rule-of-thumb methods may be called technology. He also was an important person in the community in which he lived; a little more addicted, perhaps, to whimsical opinions as a substitute for wisdom; but that followed his rule-of-thumb technology, which was not even supposed to be understandable. He was a good citizen and an independent thinker, according to his lights.

These men are passing away, because both commerce and industry are passing over into the hands of bankers. The development of great corporations which have replaced private and personal ownership has placed bankers and lawyers in command. They select directors, chairmen of the boards and presidents. In many industries we find men in control who cannot look or even think beyond the balance sheet. And since accounts are only records of past performances, they cannot see ahead. They are ignorant of the technology of the industries which they direct, and as for the science which underlies the technology they are no better informed than so many hod-carriers. We do not say this of all men in industry, but we do affirm it in relation to so large a number as to threaten our national welfare in industry.

Let's follow out a frequent process: Imagine please, a product greatly needed which is worked out after long and tireless investigation, and the inventor, a scientific man, is associated with a business man who grows in understanding as the venture develops. The demand for the product is so great that they need money for extensions. Their bank of deposit will deal only on their notes, and they want to fund their floating debt and to double or treble their capacity. So they go to the investment banker. At this point the sound

economies which they have always practiced are likely to get a severe jolt. The more money they need the more welcome they are. The broker plans a bond issue, a preferred stock issue and common stock eruption of about the current value per share of German marks. The banker keeps an inordinate share of preferred and common stocks as commissions, but it is a good thing, and the two old boys go on working and planning and directing the corporation's affairs with an unwieldy board of directors, strangers to the business, and hopelessly ignorant. The banker appoints his favorite firm of public accountants to balance the books and with that he feels secure. "The books," he declares cheerfully, "tell the whole story." He can understand the balance sheet; and that is all that he can understand. One director gets his favorite insurance broker appointed, and another places his son-in-law in the office. But the two old boys stick to their jobs and all goes so well that the common stock begins to have value, and we read the quotations in the newspapers. It looks like a good buy.

Then comes the chance for amalgamation, consolidation and a new stock issue. Why not? If grocers buy both flour and sugar, then a consolidation of sugar and flour industries is a proposal of the sort that appeals to the banking eye. It will save duplication of sales force and fill up freight cars to sell more sugar and flour together than of either commodity alone. And in a reorganization there are more commissions which are pleasant to consider. So this particular industry is tied up with something else—"related," as the bankers say—and the consolidation makes it so big that the stockbrokers begin to talk about it. The two old boys cannot see it; they don't know these other lines of business that are coming in; they say they are too old to learn new tricks and so they are bought out because they are not progressive. Then the banker takes hold for fair. He wants a good administrator as president and as likely as not he will get a man who has succeeded in developing a string of 5 and 10 cent stores and will expect him to manufacture this particular product which requires at every step in the process trained, scientific control. "He's got a good business head," says the banker, "and that's what we want here."

True, the new administrator knows the 5 and 10 cent business down to the ground, and the very fact that he has succeeded in it is his worst quality. You can't fool him in the 5 and 10 cent store business but you can put all sorts of foolish notions over on him about this new business, because he does not understand it fundamentally. Little wrong guesses turn out to be thundering mistakes. He is lost in his job because he is befogged with ignorance, and genius itself can't see through a fog. So there is danger ahead. He brings fog and mud instead of a clear vision ahead and a well-thought-out road of progress. Then old Uncle Trouble and Aunt Agony come and settle down as members of the family.

The remedy is easy if it can only be got into the minds of investment bankers. They don't know how to seek information. Their business is that of super-treasurer of the corporations they organize and they do not play the game straight. They do not give value received in honest study and in getting information and in constructive thought in return for what they get out of it. They want the big profits without contributing enough real work. This is their minor fault. Their major fault is that they put the wrong men into ad-

ministration. That is due to their inexcusable ignorance, which they can remedy by study and work. They don't study enough or know enough. If they haven't got the time to learn, or the educational backing to make themselves familiar with the business, they should leave well enough alone—or at least they should learn how to seek advice. It is easy enough to take advice—the difficulty lies in finding out where to get it.

A Notable Movement

In Metallurgical Education

A DEFINITE educational movement for the benefit of the "man at the fire" is one of the fundamental aims of the American Society for Steel Treating. Not only is this aim stated in the constitution of the society, but the national officers bear this responsibility in mind. This in turn is doubtless due to a constant urge from the membership, voiced through the officers of the thirty-one local sections, or chapters, so called. All the directors realize that the phenomenal growth of the society has risen from a desire on the part of the skilled heat-treater to acquire some technical and theoretical information on his daily work. This desire must not be disappointed; otherwise the decline of the society will be as rapid as its rise.

A most pretentious effort in educational lines is sponsored by the important chapter at Chicago. Over a year ago they induced the president of Lewis Institute to provide facilities for an evening course in metallurgy, and secured the services of Professor JOHN F. KELLER, of Purdue, to direct the work. Several specialists also volunteered to lecture on certain phases of heat-treatment. This effort proved such a gratifying success that now two separate courses are offered, one on heat-treatment and the other on metallography of iron and steel, each extending over four months, and meeting for three hours two evenings each week.

Such a program is obviously not beyond the resources of many of our technical colleges, and it appears to be one well worthy of imitation. However, other local sections, notably those at New Haven, New York and Bethlehem, did not wait to perfect a working arrangement with some progressive school, but have laid out a well-considered program to occupy the regular monthly meetings; a program which will cover certain branches of the art in a systematic manner, each meeting to be addressed, in not too technical language, by an undoubted authority in his subject. The New Haven chapter demonstrated last year that such a series of meetings was very popular with the members. Knowing that the new president of the society, P. H. GILLIGAN, is a New Haven man, it is unnecessary to remark that his influence will undoubtedly support those members who desire to perform some service for brothers less fortunate in their technical education.

Nor should such meetings be devoid of interest to the skillful metallurgist. One has only to read Professor TYNDALL'S fascinating lectures to know that it is possible to instruct both the expert and the layman. Of course, there are few Tyndalls, but now and then the feat so easy for him, so difficult for others, is attained; witness Dr. JOHN A. MATHEWS' masterful address recently given in New York on "What Is Steel?" Commonplace facts stated with precision and interpreted with that discrimination which comes unbidden from many years' experience gives not only instruction to the tyro but a new perspective to the specialist.

Foundations of Trade Unionism

THE very familiar question of which came first, the chicken or the egg, has a sort of parallel in this matter of trade unionism. Is a shop union because the employees are union men, or are the employees union men because the shop is union? Sometimes an employer finds he can't get employees unless he signs the scale and sometimes a man can't get a job unless he has a union card. In branches of the building trades these cards frequently cost \$100 to \$200 apiece. Sometimes, and fortunately more frequently, the shop is "open" and there is no question about unionism. The employer picks out the best men to employ, and a man gets a job if he is good enough.

The question of which is cause rather than effect has been brought prominently before the public by the advertising which the "check-off" in the bituminous coal industry received last week through the granting of an injunction against coal operators using this system. The check-off, instituted a couple of decades or so ago, is a sort of automatic unionism. The scale signed by the operators requires that they deduct from each man's pay his initiation fee, fines and monthly dues and remit in lump sum to the local division of the United Mine Workers. Thus upon accepting employment a man automatically becomes a member of the union, so far as supporting it financially is concerned. If the man is not a good union man, disposed to strike when told, etc., the union can employ to educate him in unionism the funds he helps to provide.

As a system this is very efficient. All that is necessary is to get the scale signed and the rest will usually take care of itself. If there are non-union mines whose competition interferes with the operation of union mines the funds can be employed to unionize those mines, putting them in the same boat with the rest. If when a scale settlement time comes around the men want an increase in wage rates which the operators cannot afford to pay with the existing price of coal, all that is necessary is to fail to agree. Thereupon there is what is called "a cessation of mining" rather than a strike; coal becomes scarce and advances in price, and the operators are then able to pay the advance in wages. The coal operators cannot agree with one another to close their mines in order to improve the market, as that would be a violation of the Sherman law, but there is no law preventing them from disagreeing with the United Mine Workers. It is purely incidental that thereby the union mines all become idle. It is wrong to agree, but all right to disagree, and the public takes (or pays) the consequences.

It is curious, decidedly curious, indeed, that the check-off has existed so long in the bituminous coal industry and in but few other isolated instances. This is no fault of Mr. GOMPERS, for upon the granting of the injunction against the check-off last week Mr. GOMPERS promptly arose to record his protest not merely against Judge ANDERSON'S injunction on union activities in the non-union West Virginia coal field, but against the check-off injunction as well. He "could not see" why a judge interferes with the practice, the decision being "part and parcel of the attempt to repress and subdue labor." Mr. GOMPERS would find his work easier in his declining years if the check-off were made universal. He repeats his threat of the past two years, which the public will heed even less than formerly, that if his

variety of trade unionism is not encouraged the workers will adopt something worse, meaning bolshevism, etc. Mr. GOMPERS ought to have something more interesting to say by this time.

If the bituminous miners will not pay their dues except by having the money taken out of their pay, there is prospect that one of the three great monopolies that have been holding up the American people will have its power lessened. The two others are the railroad unions and the unions in the building trades.

Congress Fears Cupidity In the Chemical Industry

OUR Washington correspondent transmits this week a news item which we commend to all leaders, particularly business leaders, in the chemical industry. We have been preaching in season and out the advisability of continuing research in all our technological industries and the necessity of keeping our chemical industries in the hands of men who appreciate its technical requirements. We have consistently deplored the tendency to curtail research and have pointed out the danger of allowing our great chemical industries to fall into the hands of business men and financiers whose only yardstick is the immediate dollar and with whom success can be reflected only in the balance sheet. If practical evidence were needed to support the wisdom of our contentions, it can be found in the impression prevailing in Congress today "that the banking interests have gained the upper hand in many chemical activities and that there is a tendency to eliminate research and experimentation in the interest of greater profit." In this attitude of mind Congress will scarcely look with favor on claims of the chemical industry for tariff protection. Hitherto the House has been persuaded to recommend unusual measures for the protection of the chemical industry, but favorable consideration cannot be expected if the impression is permitted to persist that men of technical vision are being superseded by business men who look more to immediate profits than to a stabilized industry. We have all gladly joined in the effort to educate Congress to an appreciation of the importance of chemistry in our national welfare, but nobody will rally to the defense of those whose cupidity leads them to exploit a great industry. Steps should be taken immediately to set Congress right in this matter, particularly by those whose actions are responsible for the prevalent impression.

One of the great needs of American chemical industry today is a spirit of unity and solidarity through all the elements that go to make up the whole. It will not prosper if here and there through the ranks are short-sighted individuals in positions of power who consider only their own immediate welfare and make no contribution to the general good. Chemical industry as a whole is going to profit by whatever consideration it gets at the hands of Congress, and it is unfair for a few who are without vision to jeopardize the prospects of success of those who are broad-minded and far-seeing. It may be well to remember that a successful chemical industry requires the attention of chemists. It cannot be fully comprehended by bankers, promoters, stockbrokers, and so-called successful business men, and it is quite evident that Congress has been educated to a point where it realizes this fact, and will look with disfavor upon a chemical industry controlled by such elements.

British Chemical Industry

FROM OUR LONDON CORRESPONDENT

LONDON, Oct. 14, 1921.

THE slow but steady improvement in the chemical trade which developed after the holidays and which, it was expected, would continue after the coming into operation of the safeguarding of industries act has not been maintained, and at the time of writing the demand is not so active. While it cannot be said that markets have received a setback, business is not yet of a stable nature in spite of occasional evidence of considerable and somewhat spasmodic improvement. The prospect of gradual stabilization has been upset by the sudden depreciation of German currency, which has been sufficient almost to neutralize the operation of the safeguarding of industries act in regard to depreciated exchanges, in so far as it affects German imports.

ANOMALIES OF THE KEY INDUSTRIES ACT

The official list of articles chargeable with duty under the key industries act is a formidable document of seventy-three pages, and its importance to the fine chemical industry is demonstrated by the fact that this section covers fifty pages and includes about 2,500 substances, including those protected by the dyestuffs act and marked "D." While it was scarcely to be expected that this act could be operated without serious disorganization and criticism, it is already apparent that the dissatisfaction and inconvenience caused will be more severe than was expected, and not only the technical press but also the daily press is giving prominence to anomalies and complaints mainly in view of the fear of additional unemployment. The principal complaint is that numbers of articles are included which have no real relation to key industries and so give the measure a more broadly fiscal character. In addition, there is the usual unfortunate tendency of customs officials at first to interpret the letter rather than the spirit of the act. Thus importations of toy magic lanterns and eyes in dolls' heads are held up as being optical glassware, the small carbon rods used in pocket batteries are considered to be arc lamp carbons and even electric lamps containing tungsten wire originally supplied by British manufacturers cannot at present be re-imported. A joint conference is to be organized by the London Chamber of Commerce and the Chemical and Dyestuffs Traders Association with the idea of formulating an authoritative case to be laid before the government. Meanwhile the only other activity to be noted is increased advertising by the firms whose products are being protected, often accompanied by announcements of price reductions as an additional bait to the shy purchaser.

LESSONS OF THE OPPAU EXPLOSION

Nothing authoritative has yet been published in regard to the cause of the disaster at the Badische Co.'s works, but discussion of its probable effect on the nitrogen industry and theories as to its origin are rife. It is generally assumed that decomposition or overheating of ammonium nitrate or a mixture of ammonium sulphate and nitrate, either from external causes or through acidity and consequent decomposition, resulted in the ultimate explosion of the products in store and as a result there is some apprehension in regard to stocks of similar commodities at various factories here and on the Continent. There is a close

analogy between this explosion and that of a large quantity of potassium chlorate which occurred at the United Alkali Works near St. Helens in 1899. At that time potassium chlorate had not been known to explode and yet by reproducing the conditions during the fire prior to that explosion it was conclusively shown that when molten and struck a glancing blow with a piece of wood on a brick floor potassium chlorate would explode violently with the utmost regularity. The Claude process for ammonia synthesis continues to make headway and it is rumored that the British group intends ultimately to consolidate its interests by controlling Norwegian production and has in fact already acquired certain water powers from which the cyanamide industry in that country obtains its supply.

GENERAL DESPONDENCY PREVAILS REGARDING THE FUTURE

In spite of the belated legislation, it is freely predicted that the British chemical industry will ultimately revert practically to its pre-war status and importance. An exception is made of the heavy chemical industry, but it is realized that apart from state-supported key industries the chemical industry of Great Britain must in the future as in the past depend largely upon the efforts of the merchants and traders and that these must be placed in a position to maintain to the fullest extent the export and foreign trade, British manufactured goods being necessarily left to find their own level in the face of external competition. In the same way, the future of the chemist is gradually becoming an acute problem, particularly the future of those whose attainments and achievements are below the average or insufficient to warrant their retention in normal work and progress. Probably the junior chemist who lags behind in the race will have to swallow his pride and become a process-foreman or a salesman, and it is not unusual to find men with commercial ability who have become successful travelers, utilizing their technical knowledge somewhat in the way that was practiced by the representatives of German dyestuffs firms before the war. The depression in trade has also militated against the work of unifying chemical and scientific societies, which was initiated by the Federal Council, it being impossible at the moment to attract the funds for a central home. There is still so much jealousy and rivalry among the various societies that none of them can reasonably be expected to show the way without exciting suspicion. Mining engineers have succeeded in getting together and there is still the possibility that through the medium of bodies like the Chemical Industry Club or the Radium (Chemists) Lodge, the foundations can be laid for a better understanding and at any rate for the provision of a common meeting house and library. The lessons learned by the visitors to the United States and Canada are receiving due publicity and it is recognized that the organization of the American Chemical Society excels in its influence not only among chemists but on the American press and public. Meanwhile the Society of Chemical Industry appears to be going through a transition period and many changes are foreshadowed, mainly as regards policy. The crux of the matter is still that of publicity, and in addition members are clamoring for further departures from tradition and the provision of improved meetings and incidentally better entertainment than that which was afforded by the recent annual dinner.

Recent Developments in the Sulphuric-Acid Industry--I

New Methods and Equipment for the Production of Sulphur Dioxide, Precipitation of Flue Dust and Introduction of Nitrogen Oxides in Chamber Process Are Reviewed in the First of an Important Series of Articles

By ANDREW M. FAIRLIE
Consulting Chemical Engineer

ALL of the important processes for the manufacture of sulphuric acid could formerly be comprised under two general heads: the chamber process, and the contact or catalytic process. The chamber process has itself been considered by some as a kind of catalytic process, but generally it has not been so classified. The distinctive features of the chamber process have been the use of oxides of nitrogen, and of lead chambers, in combination. The recent development of processes which use no chambers, but still use oxides of nitrogen, has upset the former simple classification. These new processes certainly are not chamber processes, nor are they contact processes in the narrower meaning of the term as applied to sulphuric-acid manufacture. A new classification is therefore proposed, and inasmuch as these new processes all use oxides of nitrogen, they are grouped with the chamber process under the general head "nitration processes," leaving the contact processes as they were, in a group by themselves.

This series of articles is based on a lecture delivered by the author before the Franklin Institute of the State of Pennsylvania in the spring of 1921. It is the purpose here, as in the original lecture, to confine attention to nitration processes only, discussing the developments, since 1914, in equipment and appliances, in plant design and construction, and in plant operation. As this discussion is by nature a review, no special claim is made to presenting novelties. Many of the features described herein have appeared in the technical literature and are more or less familiar. Here we concentrate the attention, however, on developments relating to a single industry, and correlate these developments with one another. The descriptions of the devices and inventions considered are brought as nearly as possible up to date, and an opportunity is afforded, with the aid of the illustrations, to contrast or compare them.

RAW MATERIALS FOR SULPHUR DIOXIDE

Prior to 1895 most of the sulphuric acid made in this country was made directly from sulphur, or, as it is commonly called, brimstone. Then during a period of twenty years brimstone was largely supplanted by pyrites. Since 1914, however, the use of sulphur as a raw material for acid making has rapidly increased, and by 1918 the percentage of acid made from sulphur, based on the total acid made in this country, was 48 per cent.

The restrictions on importations of Spanish pyrites during the war, coupled with the extraordinary demand for sulphuric acid for the production of high explosives, gave the brimstone industry an opportunity to regain to a large extent the supremacy, as a raw material for the manufacture of sulphuric acid, which it had enjoyed

TABLE I. QUANTITIES OF SULPHURIC ACID PRODUCED IN THE UNITED STATES FROM DIFFERENT RAW MATERIALS, FOR 1914, 1917 AND 1918

	Tons 50 Deg. Bé. Acid			Per Cent of Total		
	1914	1917	1918	1914	1917	1918
From brimstone.....	100,000*	2,350,000	3,580,000	2.6	32.6	48.0
From pyrite:						
Spanish pyrite....	1,900,000	1,650,000	570,000	50.0	22.9	7.6
Domestic pyrite, including "coal brasses" and pyrrhotite.....	600,000	850,000	950,000	15.8	11.8	12.7
Canadian pyrite...	300,000	500,000	550,000	7.9	6.9	7.5
From roasting zinc ores.....	500,000	1,300,000	1,200,000	13.2	18.1	16.1
From waste gases at copper smelters.	400,000	550,000	600,000	10.5	7.7	8.1
Totals.....	3,800,000	7,200,000	7,450,000	100.0	100.0	100.0

* Approximate.

prior to 1895. Table I shows approximately the extent to which brimstone supplanted pyrites in the manufacture of sulphuric acid during the years 1917 and 1918, as compared with the year 1914.

Since the close of the war Spanish pyrites has again become available, and manufacturers are confronted with the problem, At what price per unit of sulphur contained is pyrites cheaper than brimstone, with the latter at a given price? The answer to this question cannot be found in a comparison of the cost of burning a given weight of sulphur from brimstone with the cost of burning the same weight of sulphur from pyrites. The use of pyrites for the manufacture of acid involves additional costs, as compared with brimstone, beyond the burner room. The costs of removing flue dust, of washing sediment out of tanks, towers and chambers, of acid and niter lost in washing operations and of additional niter required, the increased depreciation of chamber plant, the increase in maintenance expense, the decrease in production capacity of chamber plant, with consequent increase in cost per ton of acid for fixed charges, must all be considered. The answer to the question must be sought, then, in a comparative statement of the cost of a ton of acid made (a) from pyrites, and (b) from brimstone.

BURNER EQUIPMENT

The transition from pyrites to brimstone necessitated a change in burner equipment at many plants. Where burners for lump pyrites had been in use, the change was simple and consisted merely in installing pans in the place of the grate bars. Plants equipped with fines burners installed brimstone burners of one of the well-known mechanical types, such as the Glens Falls horizontal rotary burner, or the Vesuvius, or vertical cylindrical, burner.

*Compiled from data given by A. E. Wells and D. E. Fogg in "The Manufacture of Sulphuric Acid in the United States," Bull. 184, U. S. Bureau of Mines, pp. 23, 24.

The latter part of 1919 saw the first successful attempt to make sulphuric acid from copper converter gas. This was done at the plant of the Tennessee Copper Co., at Copperhill, Tenn., and followed close upon the heels of a rather remarkable improvement in blast-furnace practice, whereby the quantity of blast-furnace gas lost into the atmosphere was reduced to a very small percentage. The combination of the more complete recovery of the blast-furnace gas with the utilization of the converter gas increased the percentage of sulphur made into acid, based on total sulphur volatilized at the Copperhill plant, from about 70 per cent to upward of 92 per cent. For the past two years the sulphur fume nuisance has practically been eliminated at Copperhill.

Fig. 1 shows the former smoky condition of the plant

FIG. 1. CHAMBER PLANT OF TENNESSEE COPPER CO., COPPERHILL, TENN., SHOWING CONTRAST BETWEEN FORMER PARTIAL, AND LATER COMPLETE, CONDENSATION OF SULPHUROUS FUMES TO SULPHURIC ACID

of the Tennessee Copper Co. as compared with its present appearance, and clearly indicates the improvement in sulphur recovery efficiency.

The converter gas is blown into the same hot gas flue as the blast-furnace gas, and no attempt is made to keep separate the gases from the two sources. The gases mix in the brick flues, and the introduction of the converter gas has involved no serious complication in operating methods at the acid plants. The successful use of converter gas at Copperhill indicates that sulphuric acid can easily be made from converter gas alone wherever there is a sufficient number of converters in operation to insure an uninterrupted supply of gas.

DUST PRECIPITATION

Flue dust does not concern the acid maker who burns brimstone. Those who burn pyrites, however, or who

make acid as a byproduct of roasting zinc or copper ores or of copper-smelting operations, experience much trouble and expense from the dust coming over with the gas from the burners, roasters or furnaces. At some plants the burner or furnace gas carries, in addition to the dust (fine particles of the furnace or burner charge), metallic fumes, consisting of volatilized metals or metallic compounds, more or less condensed and consisting of very finely divided particles almost as hard to precipitate as the gas itself. The proportion of fume, however, is always small in comparison with the particles of burner or furnace charge, commonly called flue dust, and most acid makers would be content to put up with the fume problem if they could only be rid of the dust.

Various types of mechanical precipitators for flue dust have been briefly described in the recent bulletin by Wells and Fogg.² The same authors have referred to the use of the Cottrell electrical methods for precipitating flue dust from acid-plant gas. In the Cottrell precipitators the gases pass between two electrodes, one of which is grounded, while the other is under a high voltage, 40,000 to 60,000 volts. Two different types of Cottrell dust precipitators have been installed: the pipe treater and the plate treater. In the pipe treater, the grounded electrodes are vertical pipes and the charged electrodes are wires, one of which is suspended vertically in the center of each pipe. The gases may ascend or descend through the pipes, satisfactory distribution of the gas through all the pipes being possible in either case.

In the plate treater the grounded electrodes are parallel plates of steel or sheet iron suspended vertically and arranged parallel to the side walls of the gas flue. Between these plates the charged electrodes are suspended, and the gases either pass horizontally or rise vertically between the parallel iron or steel plates. The first installation of the plate treater had chains for the charged electrodes. More recently narrow strips of steel have been substituted for the chains, and, it is said, have been found more satisfactory. The treaters are designed to electrify the dust or condensed fume particles as the gases pass between the electrodes, so that the electrified dust or fume may be precipitated, chiefly on the grounded electrode. Means for vibrating the electrodes for the removal of accumulated dust may be provided, and the flue is preferably constructed with a hopper-shaped bottom to facilitate the removal of dust. Spare units of Cottrell treaters should always be installed, provided with suitable dampers so that when necessary to clean or repair one unit the gases can be shut off from such unit and passed through the others without interrupting plant operations.

INSTALLATIONS OF ELECTRICAL TREATERS

The initial experiments for the precipitation of dust by the Cottrell process from the hot gases of a sulphuric-acid plant were conducted at the Cleveland plant of the Grasselli Chemical Co. The commercial installations which have been installed include two treaters for the Baugh Chemical Co., Canton Works, Baltimore, Md., two treaters for the General Chemical Co., Delaware Works, and one treater each for the National Zinc Co., Kansas City, Kan., and the Grasselli Chemical Co., Cleveland, Ohio. Some of these treaters are at present not in operation due to burning brimstone in lieu of dust-forming ores. The apparatus used in each case

²Op. cit., pp. 74-75.

FIG. 2. INTERIOR VIEW OF COTTRELL DUST PRECIPITATOR, PLATE TYPE, FOR CLEANING HOT GASES FROM PYRITES BURNERS

consists of two horizontal chambers in parallel, with dampers in the inlet and outlet gas connections of each.

In the first plate treaters installed for the precipitation of dust from acid-plant gases the plates were too thin and were not ribbed sufficiently to prevent buckling in the hot gas. Trouble was also experienced in the method of supporting the discharge electrodes in the hot gases due to failure of the insulators and steel supporting beams. These difficulties, it is claimed, have been overcome by hanging the discharge electrodes on cast-iron beams and by using heavier plates with more substantial ribbing. These cast-iron beams are in turn suspended on steel tension rods passing through the roof of the flue, from which they are insulated electrically by fused silica bushings. The rods are hung from a steel framework outside the precipitator carried on tapered corrugated porcelain insulators 24 in. high.

EFFICIENCY TEST ON COTTRELL PRECIPITATOR

The right to the electrical precipitation process as applied to cleaning the gases from pyrite burners throughout the United States, with the exception of six of the far Western States, is owned and controlled by the Research Corporation, 25 West 43d St., New York City. Although plate treaters have been installed by this company at one chamber plant operating on pyrites fines, no numerical data on the efficiency of these treaters in precipitating dust are available. Efficiency tests have been made, however, on the improved type of plate treater installed at a contact sulphuric-acid plant in the East, and the data in Table II, obtained from one such test, have been furnished by the courtesy of the Research Corporation.

During this efficiency test the amount of sulphur burned out of the ore per burner per day was 9,350 lb., and as there were six burners the total sulphur burned was 56,100 lb. per day, equivalent, at 95 per cent sulphur recovery, to about 210,000 lb. of 60 deg Bé. acid. Since

TABLE II. RESULTS OF EFFICIENCY TEST ON COTTRELL DUST TREATER, PLATE TYPE

Dust and Elements in the Dust	Pounds Precipitated	Percentage Precipitated	Pounds Not Precipitated	Percentage Not Precipitated
Dust.....	1,700.00	98.94	18.25	1.06
Soluble iron.....	14.45	83.24	2.95	16.76
Arsenic.....	70.00	24.21	218.00*	75.79
Lead.....	262.00	81.59	59.00*	18.41

The partial analysis of the precipitated dust was as follows:

	Per Cent
Sulphur.....	4.17
Soluble iron.....	0.85
Lead.....	15.40
Arsenic.....	4.11
Acidity.....	5.98
Total.....	30.51

The remainder of about 70 per cent was assumed to be chiefly oxides of iron.

* This weight is evidently considered to be present in the hot gas as volatilized metallic fume, not as dust.

18.25 lb. of dust, 2.95 lb. of soluble iron, 218 lb. of arsenic and 59 lb. of lead escaped precipitation by the Cottrell apparatus, those amounts of impurities would be contained in the 210,000 lb. of 60 deg. acid, if chamber acid had been made from the gas, instead of contact acid. The percentage of impurities in the 210,000 lb. of acid would then have been:

	Per Cent
Dust ³	0.0087
Soluble iron ⁴	0.0014
Arsenic ⁴	0.1037
Lead ⁴	0.0284

It is interesting to note that the arsenic was the least efficiently precipitated, due, no doubt, to the fact that it was present in the gas chiefly as uncondensed fume, and not as dust.

The cost of such a Cottrell installation for cleaning the hot gases from pyrites burners capable of burning 30 tons of sulphur per day is given by the Research Corporation as about \$60,000. The gas volume produced by the burning of the tonnage of sulphur stated would be about 20,000 cu.ft. of gas per minute, at 1,000 deg. F. The operating cost is small. Power consumption would be 1.5 kw. for the entire installation, and the only operating labor required would be an occasional inspection by the plant electrician, and labor once a week to remove the dust from the treater.

The Research Corporation states that a 90-day test on such an installation, while treating a volume of gas of from 17,000 to 22,000 cu.ft. per minute at a temperature of from 800-1,000 deg. F., with a temperature drop through the installation of about 100-125 deg. F., has shown a dust removal of 99 per cent continuously. Fig. 2 shows the interior of a Cottrell precipitator for cleaning hot gases from pyrites burners, and Fig. 3 is a photograph of the electrical equipment employed.

SCREEN TYPE OF ELECTRICAL TREATERS

A modification of the Cottrell treater for the precipitation of dust from hot gases has been developed by R. B. Rathbun, of the American Smelting & Refining Co. The main feature of this modification, on which patents are pending, is the use of sheets of iron screen, with diamond-shaped or square meshes about 2 in. wide, placed transverse to the direction of flow of the gases, and parallel to each other, with an intervening space of about 6 in. between adjacent screens, instead of the

³Total solids in the gas at the temperature at which the gas was cleaned.

⁴Probably present as a vapor at the temperature at which the gas was cleaned.

iron plates of the treater advocated by the Research Corporation. In some instances the wire screen has been replaced by expanded metal having diamond-shaped meshes of the desired width. Midway between the sheets of screen, or of expanded metal, as the case may be, wires are suspended vertically—about 6 in. apart across the width of the flue, with alternate rows of wires staggered. The screens are the grounded electrodes, and the wires the charged electrodes. This type of treater may be called the "screen treater," to distinguish it from the Cottrell treaters of the Research Corporation. High voltage is used, as with the Cottrell treaters.

The screen treater offers the apparent advantages over the Cottrell plate treaters, (a) that the grounded electrodes are placed transverse to the direction of gas

FIG. 3. ELECTRICAL EQUIPMENT FOR USE WITH COTTRELL ELECTRICAL PRECIPITATION PROCESSES

flow instead of parallel thereto; and (b) that the screens themselves, without any electrical equipment, are of a form adapted for the precipitation of dust. From time to time the screens and wires are jarred to shake off adhering dust, and during the operation of jarring or tapping, the gases are diverted into another flue. In some cases the efficiency of the screen treater seems to have been improved by injecting a finely divided spray of sulphuric acid, at intervals, into the gas stream, and this spray lodges temporarily on the screens and wires. The screen treater is said to be in successful use at some of the plants of the American Smelting & Refining Co. for the precipitation of dust from the gases of lead-smelting furnaces, where the temperature of the gas is in the neighborhood of 400 deg. F.

The burner or furnace gases of an acid plant are, of course, much hotter than this, and the results of the application of the screen treater to gases of a temperature of 800-1,000 deg. F. will be awaited with interest.

After leaving the dust chamber, or the electrical treater, as the case may be, the hot gases pass first to the niter potting equipment, if any, and then into the Glover tower.

NITRATION EQUIPMENT

On account of the inconvenience caused by the accumulation of niter cake in the hot gas flues, there has been a tendency of late, where niter pots are used, to install these outside of the flues, and fire them with

coal. In some cases, where the gases are not hot enough to "cook" the niter efficiently, outside pots are a necessity, if pots are used at all. The coal expense has been found to amount to from 1c. to 4c. per ton of 60 deg. acid produced, and this expense is less than the losses incurred in shutting down the entire plant in order to clean niter cake out of choked gas flues. The coal fired pots have, too, proved very efficient in facilitating a quick "catching" of the process, in starting a new plant, or in starting up after a temporary shut-down.

SPRAYING NITER SOLUTION INTO CHAMBER

At some plants nitration is effected by spraying a solution of nitrate of soda through atomizing nozzles located in the lead top of the front chamber. The strength of solution used is different at different plants, but at any one plant it should not vary appreciably. Some plants use solutions as low as 13 deg. Bé., others as high as 25 deg. Bé. A solution which is too weak may result in low drips and weak acid in the front chamber, while too strong solutions may not afford sufficient flexibility in controlling the supply of niter to the best advantage. The admission of nitrate solution into the front chamber results in the formation of sulphate of soda in the acid, and in many cases this is objectionable. Failure to maintain close inspection of the atomizing efficiency of the spraying nozzles may result in streams of liquid solution falling into the acid in the pan of the front chamber, with subsequent formation of liquid nitric acid, followed by undue corrosion of the bottom lead of the chamber. Where the acid is allowed to flow from the front chamber to other chambers, this corrosion may spread throughout the entire plant.

At times when it is desired to operate the chambers at a capacity much below normal, the temperature of the front chamber may be too low to vaporize the atomized niter solution, and liquid solution may fall to the bottom of the chamber. At such times, too, the burner gases may not be hot enough to cook properly the niter in pots located inside the hot gas flue; and in such cases the outside coal-fired pots are very desirable. Spraying niter solution into the front chamber has the advantage that it is a labor-saving device. Under certain conditions it is a more desirable method of nitration than potting. Other means of nitration, such as feeding nitric acid or nitrosulphuric acid into the Glover tower, are well known.

NITRATION BY OXIDIZED AMMONIA GAS

During the war a development of the attempts to use atmospheric nitrogen for the manufacture of nitric acid, either by the cyanamide process or by modifications of the Haber process, was a successful catalytic method of oxidizing ammonia gas to oxides of nitrogen, by passing the former through incandescent platinum gauze. In the early stages of the development of this method the platinum catalyzer was electrically heated; later this external heat was found to be unnecessary. This catalytic method of oxidizing ammonia gas has been fully described by Parsons⁵ and by Perley.⁶

Information received by the author indicates that equipment for oxidizing ammonia gas has been installed

⁵Charles L. Parsons, "Commercial Oxidation of Ammonia to Nitric Acid," *J. Ind. Eng. Chem.*, vol. 11, p. 541 (June, 1919).

⁶George A. Perley, "The Commercial Oxidation of Ammonia," *J. Ind. Eng. Chem.*, vol. 12, p. 5 (January, 1920); and p. 119 (February, 1920).

at several sulphuric-acid plants in England and at one plant at least in the United States, and that the nitration of the chamber process has been effected by this means. The installation in the United States referred to was at the plant of the Ammo-Phos Corporation, a subsidiary of the American Cyanamide Co., at Warners, N. J. This equipment was installed in 1916, and has been referred to by Pranke,⁷ who gives a tabulated statement as to the efficiency of the electrically-heated catalyzers.⁸ No data are available as to the actual cost of operating this equipment, as compared with operating the usual sulphuric-acid plant niter-potting equipment, and even if such data were available, it would have to be taken into account that this particular installation was at the plant of a company which is itself a manufacturer of the raw material, and others who would have to purchase the ammonia might find themselves in a less favorable position.

The catalyzers developed by the Government at Nitrate Plant No. 1, Sheffield, Ala., dispensed with the equipment for electrically heating the platinum gauze, and it is claimed that the oxidizing efficiency of the improved catalyzers has been brought up to 95 per cent and higher. Costs for operating labor are very much less with the ammonia oxidation equipment than with niter-potting equipment. Over a period of 22 years, according to The Barrett Co., of New York City, nitrogen as ammonia has cost slightly more per unit than nitrogen as nitrate of soda; but if ammonia can be bought on a sliding scale on an approximate parity with prevailing prices for nitrogen as nitrate of soda, the cost of the raw material should not be an important factor.

FACTORS TO BE CONSIDERED IN SUBSTITUTING AMMONIA OXIDATION FOR NITER POTTING

For those acid manufacturers who are contemplating a change from niter potting to ammonia oxidation, some of the important features to consider are:

1. First cost of plant, as compared with cost of niter-potting equipment.
2. Comparative costs of maintenance of plant.
3. Comparative rate of depreciation of plant.
4. Relative cost of raw materials per unit of nitrogen contained.
5. Comparative efficiency, in producing oxides of nitrogen, of ammonia oxidation apparatus versus niter pots.
6. Comparative cost of operating labor.
7. Comparison of freedom from interruptions, in service, of the two types of equipment.
8. Ability to obtain an adequate and unfailing supply of ammonia, delivered in the quantities and at the times required, to insure uninterrupted operation of the ammonia oxidation apparatus after having once installed it. (The maintenance of a niter-potting equipment as a reserve should not be considered.)
9. Probability of wastage of liquid ammonia and of ammonia gas, through leaks and spills, as compared with wastage of nitrate of soda.
10. Actual arrangements, ascertained by inquiry of the ammonia dealers, which it is possible to make in this country for the purchase of ammonia, either as sulphate or as liquor, over a period of years.

Corrosion Protective Action of Certain Colloidal Solutions

BY WILBERT J. HUFF*

IN CONNECTION with an investigation concerning the causes and prevention of after-corrosion in the bores of firearms, information was obtained upon corrosion beneath oil films. It appeared advisable to supplement this information with additional experiments and to present the whole.

Oils of many types are universally employed for the temporary protection of bright iron and steel surfaces and have, in general, proved adequate. Nevertheless, repeated examples have shown that ordinary oil coatings may fail almost completely. The circumstances surrounding such failures are generally interesting and sometimes puzzling. The writer recently received the complaint that the physical condition of the workman appeared to influence the protective action of petrolatum, for polished steel surfaces packed beneath a coating of this by one workman corroded more frequently than similar surfaces packed by another. The corrosion sometimes traced finger prints. Rifle parts handled by persons afflicted with gout are said to corrode in spite of careful cleaning and oiling.

MECHANISM OF CORROSION UNDER OIL FILMS

In a paper¹ already published the writer has shown that ordinary oils alone possess no value for the protection of the bores of firearms against after-corrosion following use. Oil films are permeable to water vapor and their anti-corrosive action rests upon the preferential wetting of the metal by the liquid oil which thus interposes a non-conducting film between liquid water and the metal. In the absence of contact between the liquid water and the metal, corrosion cannot occur. The discharge of the firearm deposits a water-soluble compound (potassium chloride) over the bore surface. Exposed to a rather high humidity, this compound deliquesces beneath ordinary oil and so forms a corrosive aqueous film in direct contact with the metal.

This mechanism applies to many cases of corrosion beneath oil films. A water-soluble salt (sodium chloride) is an important part of perspiration residues, hence the finger prints. The excretion of perspiration is dependent upon physiological conditions which vary to some extent from worker to worker, hence the personality factor.

Corrosion under oil caused by corrosive water-soluble compounds presents very important problems. A vast number of manufacturing, assembling and packing operations involve handling, with the concomitant danger of salty perspiration residues. Moreover, similar forms of corrosion may be expected where iron or steel surfaces are exposed to finely divided salts carried mechanically through the air (a common condition near the ocean and in the presence of certain manufacturing operations) or where such surfaces are exposed to certain volatile water-soluble compounds.

A second serious menace presented by such water-soluble compounds is their ability to form corrosive

liquid films at humidities which may be much below that humidity at which clean iron and steel corrode.¹

Were all the surfaces upon which the water-soluble compound is deposited accessible, the prevention of such corrosion would be a relatively simple matter. Such surfaces can be given a thorough preliminary washing with water, followed by wiping. They may then be oiled with safety. Drying by evaporation following the use of tap water is not to be recommended, since such water contains salts which would thus be deposited upon the metal surfaces. Unfortunately, the bright surfaces of many assembled parts are so inaccessible that it is impossible to wipe them dry.

Experiments given below show that the water may be absorbed into a suitable emulsion. Such emulsions are almost ideal agents, for they are non-corrosive and may be readily forced over very inaccessible surfaces.

Six plates 2.5 x 3 x 0.2 cm. were cut from the same piece of steel and machined to a uniform surface. They were all carefully washed with soap and water, a hot 10 per cent solution of sodium carbonate, distilled water, alcohol and finally ether, in the order given. They

TABLE I. ANTI-CORROSIVE ACTION OF CERTAIN EMULSIONS WHEN AN EXCESS OF THE EMULSION IS IN CONTACT WITH THE STEEL

Plate No.	Medium	Change in Weight	
		First Exposure Two Days	Second Exposure Five Days
1	Ammonium oleate plus water	Gain 0.5 mg.	No change
2	Ammonium oleate plus water	Loss 0.1 mg.	Loss 0.1 mg.
3	Water-oil emulsion	Gain 0.1 mg.	Loss 0.3 mg.
4	Water-oil emulsion	Gain 0.2 mg.	No change
5	Distilled water	Loss 12.5 mg.	Loss 28.3 mg.
6	Distilled water	Loss 12.5 mg.	Loss 27.1 mg.

were then carefully weighed. Two were suspended in distilled water, two in an emulsion of ammonium oleate two parts and water one hundred parts, and two in an emulsion of one volume of the above ammonium oleate solution with one volume of neutral transformer oil (sp.gr. 0.855 at 15.5 deg. C.). The depth of immersion and the access of light and of air were identical in all three systems.

Throughout both exposures, plates 1, 2, 3 and 4 maintained their initial polish. Table I shows that bright steel surfaces may be left in contact with an excess of either emulsion safely for many days. After the second exposure all six plates were immersed in their respective solutions for an hour, then exposed to a laboratory atmosphere for twenty-seven days. At the end of that time all adhering material was removed and the change in weight determined.

The loss of weight of plates 1 and 2 was due to the formation of iron oleate, which was readily loosened, leaving the luster of the surface somewhat dimmed. The slight loss of weight of plates 3 and 4 was due to the formation of a trace of iron oleate. Under the conditions of Table II the emulsion containing oil is much to be preferred to the ammonium oleate-water emulsion. This may be due to the lower concentration of free oleic acid in the adhering film.

A comparison of the results shown in Tables I and II for plates 1, 2, 3 and 4 shows that a large amount of water may, under some conditions, aid in preventing attack. The chief loss in the conditions of Table I to give these of Table II is water, since the soap, oleic acid and oil are only slightly, if at all, volatile, and it will be shown below that the possible loss of free ammonia in itself is probably not of much consequence.

The anti-corrosive properties of ammonium soap solution shown above are apparently not unusual, for sodium

and potassium soaps in distilled water likewise prevent corrosion. This is true even in the presence of an excess of oleic acid. It is possible that other emulsions superior to the ammonium soap solutions studied could be prepared by the aid of other soaps.

Although not specially investigated, observations indicated that these soap solutions and emulsions hold their anti-corrosive properties in the presence of low concentrations of corrosive salts. However, it is not safe to allow the concentration of such salts to rise while the mixture is in contact with iron and steel surfaces, for by evaporation, concentrations can be reached at which corrosion results. Thus a piece of steel immersed in a solution of potassium chloride (1 per cent) containing a sodium soap (about 2 per cent), then exposed to evaporation, gave characteristic pitting rust so often noted in salt corrosion. A second piece immersed in a solution of the same soap (about 2 per cent) in distilled water, then exposed to evaporation, remained perfectly bright under analogous conditions.

The protective action of the soap solutions and emulsions can hardly be due to their alkalinity, for the ammonium soap solution used in the above experiments retained its anti-corrosive properties after air had been blown through it for several days to drive out any ammonia which might have been formed by hydrolysis. A better explanation suggests the preferential coating of the metal surface by the colloid or oil, resulting in the formation of a non-conducting film. This preferential coating action probably explains the anti-corrosive action of oils to which certain peptizing agents

TABLE II. ACTION OF CERTAIN EMULSION RESIDUES WHEN ALLOWED TO EVAPORATE IN CONTACT WITH STEEL

Plate No.	Medium With Which the Plate Was Initially Coated	Change in Weight
1	Ammonium oleate, plus water.....	Loss 2.8 mg.
2	Ammonium oleate plus water.....	Loss 2.5 mg.
3	Oil-water emulsion.....	Loss 0.3 mg.
4	Oil-water emulsion.....	Loss 0.4 mg.
5	Distilled water.....	Gain 0.1 mg.
6	Distilled water.....	Gain 0.5 mg.

have been added. Exposed to the atmosphere, under certain conditions, such a mixture takes up sufficient water to form an emulsion, the aqueous phase of which dissolves the corrosive compound. The use of such oil-peptizing mixture is not, however, entirely satisfactory, since the supply of compound may be relatively large or the rate of supply of moisture from the atmosphere relatively small, thus permitting the formation of a concentrated electrolyte which may not emulsify readily, but may instead remain in contact with the metal at some point and so cause corrosion. A somewhat more satisfactory expedient is to use an emulsion containing considerable water, thus insuring a low concentration of salt in the aqueous phase. Here, again, the expedient is not ideal, for the vapor pressure of the aqueous phase may endanger a portion of the metal not protected by actual contact with the oil or colloid. Moreover, a low atmospheric humidity may so concentrate the emulsion that this may break and deposit a corrosive residue in contact with the metal.

At present it is believed that thorough washing with water, followed immediately by a careful rinsing with a suitable emulsion and lastly by a coating of oil, is the best treatment available for the temporary protection of inaccessible bright steel surfaces.

Nitrogen in Carburized Steels

Nitrogen Plays a More Important Role in Everyday Metallurgy Than Is Generally Supposed—Many Commercial Carburizers Introduce Considerable Amounts of This Element—Micrographic Methods for the Detection of Nitrogen Compounds Worked Out and Described

BY W. E. RUDER AND G. R. BROPHY
Research Laboratory, General Electric Co.

THE presence of nitrogen in steel under certain conditions has been recognized for forty years, although little attention was paid to its effect until 1905, when Braune and later Strauss studied its effect in quantities greater than those ordinarily found in commercial practice.¹ Since the revival of interest in the effect of nitrogen, due to the study of its marked influence upon the ductility of electric arc welds, its presence in at least two other important conditions has been suggested. Lieutenant Wheeler² and Knight³ have advanced a most plausible theory that nitrogen is the active agent in the hardening and erosion of gun liners. Brophy and Leiter⁴ demonstrated that case-hardening by the cyanide process is largely a nitroge-nizing rather than a carburizing process.

The work reported in this paper is a continuation of this latter investigation and deals with the introduction of nitrogen by solid carburizers such as are largely used commercially, and the effect of various elements often found in alloy steels.

ETCHING FOR NITROGEN

The presence of nitrogen may frequently be detected by the nitride needles which are quite characteristic,

but when it is present as a solid solution in the ferrite or as a eutectoid (possibly between FeN and Fe) its presence may easily be overlooked. In the latter form it resembles an imperfect form of pearlite.

Heat-tinting gives a clue to its presence when dissolved in the ferrite, as ferrite grains containing dissolved nitride color much more rapidly than pure ferrite.

In order to distinguish between nitrogen patches and pearlite a $\text{CuCl}_2 + \text{HCl}$ reagent was developed which has given excellent results. This has already been briefly described⁵. The sample is polished in the usual manner, after which it is washed and dried carefully with a soft cloth. Stead's (phosphorus) reagent has been found to have about the right proportions of Cu and HCl and since it is one usually found in all metallographic laboratories is recommended for use. The proportions are 2.5 g. CuCl_2 , 10 g. MgCl_2 , 6.25 c.c. HCl and 250 c.c. $\text{C}_2\text{H}_5\text{OH}$. Just enough hot water is used to dissolve the MgCl_2 and CuCl_2 . The surface of the sample is covered with the reagent, and as soon as a copper deposit shows on the surface the sample is washed, dipped into hot water and dried with a single blast of compressed air. The washing and drying must be performed rapidly or there is danger of discolora-

FIG. 3. MICROSTRUCTURE OF CYANIDED ALLOY STEELS. ETCHED WITH HNO_3 . $\times 200$

tion, leading to erroneous conclusions. The etching solution must not be permitted to dry on the surface—more solution should be added if the deposit is slow in forming.

When properly etched the ferrite is covered with copper, the cementite remains bright and the pearlite is also white. The nitride needles and the white (nitride?) hard constituent of the eutectoid patch are black. On further etching the pearlite also becomes copper plated, but the cementite remains white and the nitride etches out and, in appearance, remains dark. If the sample has been previously etched with nitric or picric acid, it should be repolished before applying this reagent.

Comstock⁶ finds that the use of an additional reagent aids in making the distinction more certain. He suggests boiling the specimen for 10 to 30 minutes in a reagent, 10 g. KOH and 1 to 4 g. $\text{K}_3\text{Fe}(\text{CN})_6$, dissolved in 100 c.c. of water. With this treatment cementite is blackened, pearlite and sorbite are turned brown and the "massive" nitride constituent is unchanged or at most slightly stained. In our experience this latter treatment has rarely been found necessary.

It is to be noted that this use of a cupric reagent is distinctly different from other applications of this versatile metallographic reagent. It has been used for

⁶Discussion, "Nitrogen in Steel," *Mining and Metallurgy*, No. 160, April, 1920.

the detection of phosphorus, nickel, cobalt, tin, antimony, silicon, carbon and oxygen when present in solid solution.⁷ In such cases it owes its value to the fact that solid solutions of these elements in iron are electro-positive to pure iron and remain white while copper is deposited on pure ferrite. In the case of the nitrogen compounds the action is more positive, as they are actually attacked by the reagent and blackened. Heat-tinting colors nitrogen areas first, in this resembling the action of other elements such as phosphorus. Oxygen existing in solid solution or around the grain boundaries is also distinguished from nitrogen, which often exists in the same position, by the fact that oxygen areas remain white, while nitrogen areas turn dark.

NITROGEN INTRODUCED BY CASE-HARDENING

Many case-hardening operations, especially cyaniding, introduce varying amounts of nitrogen. It has been shown that the hardness was largely due to nitrogen and not alone to the 0.30 per cent C introduced, which is not sufficient to cause the hardness found. The action of N_2 , as far as our experiments have gone, is very much like that of carbon, and the resulting structures are very much alike. The copper reagent makes a clear distinction, but does not photograph well. However, after some experience nital etching is sufficiently good, as the forms of patches and needles are characteristic. The patch and needle structure are formed best after annealing.

Case-hardening appears to consist of two distinct elements: (1) Nitrogenizing—the most important hardening element in cyaniding, whether the molten, gas or cyanamide process is used—and (2) carburizing—when solid or gaseous carburizer are used which do not contain too much of the nitrogen-bearing “energizers.”

COMMERCIAL CARBURIZERS

Nitrogenous materials are very often added to commercial carburizers on the assumption that they aid in the penetration of the carbon. We know now, however, that this is not the case. The effect is one of additional hardness, due to combined nitrogen. This nitrogen penetrates deep into the specimen, and nitrogen needles are found inside the case proper. The brittle-

ness caused by this nitrogen may well be the cause of numerous and perplexing cases of exfoliation.

Through the courtesy of several well-known manufacturers of carburizing compounds, samples were obtained and carbonless iron rods were carburized in them. Resulting structures are shown in Fig. 1. Each section represents a different brand of carburizer. A and B are very high in N, being obtained with green bone and leather, respectively; C and D have small amounts of N and E and F are entirely free of N. All of these micrographs are of spots in the “needle zone” of the case which is at the boundary between case and core. A and B, at 200 diameters, are practically pure nitrogen cases obtained with green bone and leather, respectively. In C and D, at 500 diameters, attention is called to the “angular” shape of the pearlite; it is also not well laminated. These points, particularly the former, are characteristic of pearlite which

FIG. 4.

A and B, microstructure of cyanided Cr-V steels. $\times 200$. C and D, microstructure of cyanided manganese steels. $\times 200$.

contains nitrogen. The needles in the ferrite are unmistakable. *C* to *F* are of higher power (500 diameters) than *A* and *B*, to bring out the structure of the pearlite.

DETECTION OF NITROGEN IN CARBON STEELS

Small amounts of nitrogen in the presence of considerable carbon are difficult to detect micrographically. Its effect upon the structure and form of the pearlite is, however, quite marked. (See Figs. 2*E* and 6.)

A series of steels were packed in the same container in charred leather and heated to 900 deg. C. for 3 hours and cooled slowly. As has been shown, heating in charred leather introduces a large quantity of nitrogen as well as carbon in the steel. Fig. 2*A* is of carbonless, hydrogen fused, electrolytic iron, swaged to $\frac{1}{4}$ in. rod, copper plated to prevent carbon penetration and treated as above. The dark patches are nitride patches, numerous needles occurring between. The structure of the patch is shown in detail in micrograph 2*F*. There is a certain resemblance to pearlite; but the dark areas are not truly laminated and are more angular and surrounded by the characteristic hard, white border. It is interesting to note here that copper-plating prevents the penetration of carbon, but not of nitrogen. This may account for the fact that copper-plating often fails to prevent hardening of the steel. If no nitrogen is present in the carburizer used, the copper will prevent any hardening.

Micrograph 2*B* shows a 0.50 C steel treated as above except with no copper-plate.

Numerous needles appear between the grains of pearlite for about $\frac{1}{16}$ in. in from the surface. On the surface is a light-colored constituent which looks like decarbonized metal, but decarbonization under these conditions is not likely to occur. Micrograph 2*E* shows a higher power of this border. The pearlite has lost its laminated structure and a hard, white constituent like "massive" cementite and numerous needles are found.

Fig 2*C* shows a 0.90 C steel after treatment. The border is not as wide as in the 0.50 C steel, and no needles appear among the pearlite grains. 2*D* is a higher power of this border. It has more of the hard, white constituent and hardly any pearlite or nitrite patches.

It appears, therefore, that as the percentage of carbon increases the penetration of nitrogen decreases and that the nitrogen tends to hold the carbon in solution, forming a hard, white constituent resembling cementite. This confirms the experiments of Andrew,⁸ who found that N suppressed and lowered the Ar₁ point and of Wheeler,⁹ who found that white cast iron showed no penetration of N when heated in ammonia. There is, therefore, great danger from brittleness involved in the use of nitrogen-bearing carburizers for treating medium and high carbon steels.

ACTION OF NITROGEN ON NICKEL STEELS

Carbonless iron alloys were prepared containing various amounts of nickel. These were swaged to $\frac{1}{4}$ -in. rods, and cyanided for 3 hours at 800 deg. C. to study the effect of nickel on the penetration and metallographic appearance of nitrogen. (Fig. 3.) In the case of an alloy containing 0.5 per cent Ni the penetration is deep (0.060 in.), the Ni having offered prac-

Three per cent vanadium steel, below.

tically no resistance to the penetration of nitrogen, which occurs in the characteristic patches and needles. The carbon of this case is no higher than 0.30 per cent, but the case was much harder than this amount of carbon would account for. The nitrogen has refined the grain of the case to a great extent compared to the large coarse grain of the center, shown in lower part of micrograph.

In the 1 per cent Ni steel the patches of nitride do not occur as deeply, but the area in which needles

⁸T. H. Andrew, *J. Iron and Steel Inst.*, vol. 86, p. 210 (1921).

⁹See footnote 2.

occur is wider, the needles more numerous and the grain is finer. The "penetration" is the same as in 0.5 per cent Ni.

At 2 per cent Ni fewer patches occur and very few needles are seen, but the grain refinement occurs to the same depth as before.

At 3 per cent nickel no patches or needles are seen. Judging by first appearance, there has been no penetration, but on close scrutiny a great difference is seen between the grain size of the case and core. This case is the same thickness (0.060 in.) as in the three preceding examples. The line of change is indicated by the arrow. (Fig. 3, top row, right.)

Nickel, therefore, up to 3 per cent appears to have no effect upon the penetration of nitrogen. The grain size decreases with increasing nickel, as might be expected. The change in metallographic appearance—that is, disappearance of needles and large dark patches—is partly due to this reduction in grain size, but examination under high power discloses an entire change in structure, like that in Fig. 7D of the carbon series, indicating that the nickel increases the solubility of the ferrite for nitrogen and what carbon there is present.

CHROMIUM STEEL

This series was made up, treated just as described in the nickel series, and shown in the middle row of Fig. 3. The penetration is about the same as with nickel. The concentration is greater, however, in all cases and may be due to the greater affinity of Cr for carbon or nitrogen or both. With 2 per cent Cr a decided network appears, increasing in width with increased Cr content. Chromium appears to increase both the penetration and concentration of nitrogen as well as carbon.

VANADIUM STEEL

This element is more active than chromium. The concentration is greater and the hyper-eutectoid zone wider with 3 per cent vanadium than with 3 per cent chromium. (Fig. 3, lower row.) Inserts show photographs of fractures of these three series, the depth of penetration being the same in all regardless of amount or kind of special element.

CHROMIUM-VANADIUM STEEL

A combination of these elements gives the expected result, both penetration and concentration being high. (Fig. 4A and B.)

MANGANESE STEEL

The absorption of nitrogen is high in manganese iron alloys, and of all steels worked with, these are the most brittle after cyaniding. (Fig. 4C and D.)

COMMERCIAL STEELS

Fig. 5 shows various alloy steels containing carbon and cyanided as described above. The carbon has not prevented the special element from exerting its effect.

CARBON CONTENT OF CYANIDED CASES

Analyses of the outer 0.010 in. of the rods shown in Fig. 3, containing 3 per cent Cr, 3 per cent Ni and 3 per cent V respectively, showed 0.34 per cent C in the Cr alloy, 0.24 per cent C in the Ni alloy and 0.39 per cent C in the V alloy, certainly much too small an amount alone to account for the structure shown or hardness obtained.

The difference in structure with nital etching between carburized (no nitrogen present) and cyanided

FIG. 7. STRUCTURE CAUSED IN PURE IRON BY PURE AMMONIA (LEFT) AS COMPARED TO THAT DUE TO COMMERCIAL AMMONIA (RIGHT). $\times 200$
Annealed at 450 deg. C., above, and at 650 deg. C., below.

cases is shown in Fig. 6. The carburized cases are about five times the depth of the cyanided case. The section shown is in the eutectoid zone.

CARBON IN NITROGENIZED IRON (NH_3)

Many investigators have assumed that the dark areas herein referred to as "eutectoid" patches must of necessity contain carbon. Strauss first suggested this in working with pure iron treated in ammonia, assuming that the C came from pyridin existing as an impurity in the ammonia. In order to investigate this further two rods of pure iron were treated in tank ammonia and in pure NH_3 . The tank (commercial) ammonia did show a wider black border than the pure ammonia (see Fig. 7), but even with the pure ammonia a distinct black border of "eutectoid" structure was found. It appears that the carbon, if present, does associate itself with this "eutectoid" constituent, but that the presence of C is not necessary to its existence.

SUMMARY

Nitrogen plays an important rôle in case-hardening and greatly reduces the ductility of pieces so treated. Cyaniding is effective in introducing nitrogen, but certain commercial solid carburizers introduce nitrogen to a harmful extent. Nitrogen is not unlike carbon in its micrographic appearance and its action in the presence of added elements such as Cr, V, Ni and Mn, but its micrographic occurrence may be distinguished by the use of Stead's CuCl_2 reagent, used as described.

Schenectady, N. Y.

Legal Notes

BY WELLINGTON GUSTIN

Pearse Patent Held Anticipated and Void by District Court

In the case of the Chipman Chemical Engineering Co., Inc., vs. the Reade Manufacturing Co., the United States District Court for New Jersey held Pearse patent No. 873,680, dated Dec. 10, 1907, void for lack of novelty. Complainant had charged that the patent had been infringed by defendant and asked for an injunction, which was denied. (270 Fed., 679.)

Complainant was in the business of spraying railway tracks with a liquid weed killer by means of the device made under the patent in suit, and during the year 1918 it used 281,320 gal. of liquid on such railways as the Chicago & Northwestern, Lehigh Valley, Baltimore & Ohio, Illinois Central, Southern Pacific, Pennsylvania and others. Defendant was in the same business many years prior to the entrance into it of the complainant.

Complaint was infringement of the fifth and eighth claims of the patent. The fifth claim by analysis consists of three parts—the tank, a discharge device and a means for using pressure. Its eighth claim, in addition to the discharge device, consists of a nozzle pipe with a series of nozzles connected therewith, each containing an independent valve controlling the passage of liquid therefrom. Defendant asserts there is no novelty in either of these claims. Various earlier patents are cited, and Bradford patent No. 803,090, for a hand-car device for destroying weeds along the railroad, the court said, appeared to be a complete anticipation of the patent in suit.

Sale of Goods Before Organization of Company

The Circuit Court of Appeals of the United States, Fifth Circuit, was unable to decide the rights of the parties on questions of law in the case of Bickmore Nitrating Cotton Co. against the Covington Cotton Oil Co. (271 Fed., 80) and remanded the case for a new trial.

The Nitrating company brought suit to recover damages for breach of a contract for the sale and further delivery to it by the Cotton Oil company of 500 bales of cottonseed linters. Defendant admitted the execution of the contract and that plaintiff had lost profits in the amount claimed as damages, but defended on the ground that it was induced to enter into the contract by false and fraudulent representation of plaintiff's financial responsibility, in that it was at the time of the contract a corporation fully organized, with a paid-in capital stock of \$5,000; and that at the discovery of the true facts, defendant elected to, and did, rescind the contract.

The contract was negotiated through a broker who was uncertain whether plaintiff's manager stated the amount of the paid-in capital stock was \$5,000 or \$10,000. There was much conflict in the evidence between the parties in the issues involved. The court held that the difference of \$5,000 as alleged in the answer, and \$10,000 as given in the evidence as to the amount of capital stock paid in, was no material variance, the gist of the defense being false representation.

It appears that the Nitrating company was only in

process of organization at the date of the contract. Its organization meeting had not then been held, according to all the evidence. Plaintiff admitted that only \$500 of its capital stock had been paid in at the time of organization, and that no more than that had been paid in at the time of the negotiations of sale.

Plaintiff was given judgment in the trial court and sought to defend that judgment on the appeal by contending that proof that no capital stock, or a less amount than \$10,000, had been paid in was of no avail, since defendant rescinded the sales contract on the ground that the representation to it was that plaintiff's capital stock had been paid in to the amount of \$10,000.

However, the court pointed out that defendant's letter rescinding the sale did not lay as much stress upon the amount of the capital stock as it did upon the circumstances that there was no capital stock paid in, no corporation organized and no financial responsibility behind plaintiff's obligations.

The court said it could not be well argued that defendant was seeking to save itself from a losing bargain, since it was shown that the price of the linters as sold had not advanced, and were afterward sold to others at the same price as to plaintiff.

On the dispute as to the facts, the court said a new trial was necessary.

Trader May Announce in Advance Circumstances Under Which He Will Refuse to Sell

In a recent suit by the Andrew Jergens Co. against William A. Woodbury Distributors, Inc., for infringement of its claimed rights to the exclusive use of the name "Woodbury" and the registered trade-mark, consisting of a reproduction of a neckless head, upon dermatological preparations and toilet articles, the District Court of the United States for Delaware laid down the rule that the charge that complainant does not come into court with "clean hands" is not a defense which must be pleaded (271 Fed., 45).

As a counterclaim to the suit defendant stated certain facts to show that it was entitled to use the word "Woodbury" or "Woodbury's," together with the "neckless head," on certain toilet articles and preparations, and charged:

"That plaintiff . . . has threatened to and did refuse to deal with, or to sell its products, the products of plaintiff, to dealers . . . and the like, who dealt with defendant, and did otherwise intimidate dealers . . . and the like, into declining to deal with defendant."

The court said the rule to be applied to this proposition is to the effect that a trader or manufacturer may, in the absence of an intent to create or maintain a monopoly, freely exercise his own discretion as to parties with whom he will deal, and that he may announce in advance the circumstances under which he will refuse to sell.

Further the defendant likewise charged:

"That plaintiff . . . has threatened to and did refuse to deal with . . . trade journal publishers, . . . who dealt with defendant. . . ."

The court says this charge is too vague, indefinite and uncertain to show a cause of action in the defendant against the plaintiff. It may mean no more than that plaintiff declined to advertise in trade journals carrying the advertisements of the defendant, and if so, without further facts, it was acting within its rights by such refusal.

The Relation of the Chemical Engineer to the Manufacture and Application of Automobile Finishes*

Some Chemical Engineering Developments in the Paint and Varnish Industry Which Have Resulted From the Demand for the Large-Scale Manufacture and Application of Automobile Paint, Enamel and Varnish Products

BY C. D. HOLLEY, PH.D.

Director of Research, Acme White Lead & Color Works

LESS engineering, particularly chemical engineering, has been devoted to the paint and varnish industry than to any of the other modern industries of similar magnitude. As late as the beginning of the present century, at which time many of us were just beginning our professional careers, it would have been very difficult to have cited or discussed any engineering feature connected with the paint or varnish industry that was worthy of mention. Perhaps some will be inclined to challenge this statement and point to certain of the industries whose products are used in the manufacture of oils and colors, but I refer primarily to the paint and varnish industry in itself.

A late start oftentimes results in increased progress, and this is particularly true of the paint industry. It has outgrown many of its rule-of-thumb methods and procedures and is now using some genuine engineering in the manufacture of paint, enamel and varnish products and in their application.

The rapid developments in the automobile industry, especially as related to quantity production, have necessarily had their effect on the manufacture of paints and varnishes and have been perhaps the most potent influence in the development of this industry from an engineering standpoint.

Although the paint industry is frequently considered as separate from the varnish industry, both are closely connected and in the larger plants they are in fact regarded as separate departments of the same industry. The modern paint and varnish plant compares favorably as to size with the representative plants of other industries. The larger plants have a daily production capacity of 10,000 gal. or better of varnish and 12,000 to 20,000 gal. of paints and enamel products.

In the manufacture of the ordinary types of paint, of which house paint is a typical example, the liquid or

vehicle is essentially raw linseed oil, and the procedure of combining the pigments and the oil is rather elementary. In automobile finishes raw linseed oil as such is but little used, the vehicle being always in the nature of a varnish or grinding japan—i.e., composed of heat-treated oils, fused resins, metallic driers and volatile thinners, of the kinds and in the quantities the manufacturer considers necessary.

After the gums and oils have been "run" on the fire for the requisite length of time, which varies with the character of the products used and the requirements, the kettles are removed from the fire and allowed to cool until the temperature has dropped sufficiently to

FIG. 2. ALLOWING KETTLES TO COOL PRIOR TO ADDING THE VOLATILE THINNERS

permit the addition of the volatile thinners. In Fig. 1 is shown the older but still common type of varnish stack under which the gums are melted with no attempt to recover volatilized fumes. The kettles shown in Fig. 2 are being cooled in the open air. A portion of the melting and cooling room in a modern plant equipped with recovery apparatus is shown in Fig. 3. After the varnish has been thinned and is cool it is run through a press or a centrifugal clarifier and stored to age.

GRINDING PIGMENTS AND COMBINING WITH VEHICLE

The grinding of the pigments with the varnish vehicle for automobile coatings is accomplished in several types of mills. The mill most commonly used is the flat stone mill, 20 in. in diameter, the stones being water-cooled.

Recently a new type of mill has come into use. This is shown in Fig. 4. It resembles the previous type of mill, but instead of the rolls touching each other, each roll which is of granite is bedded individually in a half round block of granite, the contact between the roll and its bed furnishing the grinding surface.

After the enamel has been ground in the form of a

FIG. 1. THE OLD TYPE OF VARNISH-MAKING INSTALLATION

*Abstracted from a paper presented before the Detroit Meeting of the American Institute of Chemical Engineers, June 20, 1921.

FIG. 3. PORTION OF MELTING AND COOLING ROOM IN A MODERN VARNISH PLANT

paste, it is thinned by the addition of the requisite varnishes and volatile thinners and then strained to free it from dirt particles or else run through a clarifier. Clear varnishes, baking japans and auto coatings containing pigments of low specific gravity such as carbon or lampblack pigments are now handled by means of a clarifier.

USES FOR CENTRIFUGAL CLARIFIERS

Centrifugal clarification permits the paint manufacturer to prepare many of his automobile coatings free from dirt particles, small "liver" formations and any coarse pigment particles and therefore enables the user to obtain a smooth, uniform finish, free from specks or spots without having to rub down the coats. This treatment also enables the automobile manufacturer to keep the varnish and enamel coatings in his dipping tanks and collecting tanks continually freed from particles that would speck the surface. It has been the experience of one manufacturer that prior to the installation of such a system more than half of his finished product was returned by the inspectors for further rubbing down and afterward it was reduced to less than 5 per cent. It is very generally conceded that the introduction of centrifugal clarification in connection with modern application devices, such as the

FIG. 4. THREE-ROLL MILL FOR GRINDING PIGMENTS
1, 2, 3—Hard granite rolls, 4, 5, 6—Half-round hard granite beds leaded in cast iron.

use of the "floc," has resulted in a saving of more than 80 per cent in labor costs for finishing, to say nothing of the elimination of wastage. Fig. 5 shows a typical installation of a clarification system.

The pigment materials used in varnish manufacture or the technique of combining the vehicles with the pigments have not been discussed in detail, as these are well known and do not present any engineering practice worthy of mention in the present limited treatment of the subject.

FUME COLLECTION

There is, however, one feature in connection with the varnish industry that deserves special attention. Varnish making is a very old industry and the varnish maker has been content to go about his business without bothering himself about any chemical engineering requirements. Recently he has changed his mind, because in several instances he had his choice of closing down permanently, moving his plant at a heavy financial

FIG. 5. DIAGRAM SHOWING INSTALLATION OF CENTRIFUGAL CLARIFIERS

loss, or getting out of his trouble by resorting to the services of a chemical engineer.

Most varnish plants were built either in a manufacturing section or in the outskirts of the cities away from the residential sections, but with the growth of the cities, many of these plants have found themselves surrounded by residences, the occupants of which object to the large volumes of fumes emitted from the varnish stacks. From 10 to 25 per cent of the weight of the varnish gums used is driven off in the melting of the gums. These products of decomposition pass up the varnish stacks and are disseminated in the air in quantities that sometimes reach several thousand pounds daily.

This has necessitated the installation of an efficient fume control system whereby these fumes can be condensed as they leave the kettles or be made to enter into a chemical combination and thereby be eliminated. This has required some really ingenious chemical engineering practice, as the problem was not an easy one to solve, because of the physical and chemical nature of the fumes and because of the fact that the gums are "run" in the varnish kettles at nearly their flash point; any undue disturbance in the equilibrium of the gases in the kettle often meant a bad fire. Two views of recovery apparatus are shown in Figs. 6 and 7. These installations have proved quite successful, affording usable byproducts, and in several instances have permitted a 50 per cent reduction in the insurance premiums and, not least, have permitted the varnish maker

FIG. 6. THINNING RECOVERY APPARATUS

to continue the manufacture of his products undisturbed by the authorities.

APPLICATION OF AUTOMOBILE FINISHES

The systems of finishing and the methods of application developed by the automobile industry have a very close relation to modern engineering practice. There are many variations in details in the leading automobile plants depending on the experience of the finishers in charge, on the production schedule as related to the floor space available, on the price allowed for the job and especially on the labor- and time-saving devices installed. The last named have resulted from the research of chemical and other engineers.

Possibly no two devices have done so much toward reducing the cost of auto coatings as the "spray" and the "floc." Their introduction and use have accomplished wonders in the automobile industry in the way of quantity production, and due credit should be given the chemical engineer in bringing about the results obtained. The amount of work that can be accomplished by the spray over hand brushing varies considerably, depending upon the nature of the parts and the conditions under which the work is done. It is conservatively estimated that it does the work from a minimum of twice as fast and ranging from this figure up to seven times as fast as can be done by an experienced brush hand. It is used for applying the undercoatings on bodies, quite generally for all chassis work and more or

FIG. 7. VARNISH FUME RECOVERY APPARATUS

less on the wheel jobs. The "floc" is used for flowing on the finishing coats and in some instances the color coats on bodies and can be used on fenders and hoods as well. On open body work the cost of application has been reduced to 30 to 40 per cent of the previous cost.

DIPPING, BAKING AND DRYING

The application of baking japans by dipping and then baking at comparatively high temperatures was well understood before the automobile industry became a commercial factor. Generally the parts dipped were quite small and could therefore be easily handled. When the automobile plants went into quantity production, the application of baking japans to fenders, hoods and other parts together with the subsequent baking operations required extensive installations. Our present-day procedures are the result of extensive engineering research. Much ingenuity has been expended in labor-saving devices for dipping and protecting the dipped articles from dust while draining and then conveying them mechanically through the ovens. An intermittent conveyor and a dip used for fenders are shown in Fig. 8.

The time of baking has been shortened by systematic temperature control. The dangers of the old direct gas-fired oven with which there was always a risk that a burner might go out, fill the oven with gas and the

FIG. 8. DIPPING AUTOMOBILE FENDERS PRIOR TO ENTERING BAKING OVENS

mixture explode with disastrous consequences from ignition with another burner have been eliminated. The indirect method of heating in which each burner is inclosed in a separate combustion box with a separate vent from the oven is reasonably safe and does not contaminate with soot and other foreign particles the articles being baked. More recently electric baking ovens have come into extensive usage. I shall hold no brief for either the gas or the electric. Each have their advantages and disadvantages. There is still room for considerable improvement; in the larger baking installations the temperature is not as uniform as desirable throughout the cross-section of the oven to get maximum production. Much has already been done to overcome this trouble, and it appears to be only a question of time when a closer uniformity will be obtained.

The drying time of a paint, enamel or varnish varies with atmospheric conditions and, since it does vary, it necessarily follows that there must be at least one definite condition under which the coating in question will dry most rapidly and successfully. Moreover there are many different coatings to be dried and each coating contains different proportion of oxidizable oils.

FIG. 9. EXIT OF GAS-HEATED OVEN FOR AUTOMOBILE ENGINE PARTS

This, then, is the problem that confronted the automobile engineer and the engineers who have been developing the artificial drying systems.

When artificial drying was first considered, it was the general belief that moisture would retard rather than hasten the drying process. Investigation has proved the contrary, that definite percentages of moisture in conjunction with the heat materially increased the rate of drying over that obtained by the same degree of heat alone. The most successful method of controlling the humidity is by the so-called dew point control, which operates on the principle that the amount of moisture which air can carry at saturation is dependent on the temperature of the air. For instance, having determined that a humidity of 42 per cent at 120 deg. F. is required, it is found that this corresponds to an absolute humidity of $14\frac{1}{2}$ grains per cubic foot, which is the amount present in a cubic foot of saturated air at 90 deg. F. (dew point), and therefore the humidity control device is set at 90 deg. F., the current of air then being raised to 120 deg. F. after passing through the humidifier.

Considerable difficulty was at first experienced in obtaining uniform results with the light colors such as the light blues, yellows, grays and whites. These colors frequently showed marked variation under artificial drying from that obtained by ordinary air drying. More recent developments have proved that by varying the humidity these troubles can be overcome. For example, a light blue job dried at 130 deg. F. with 35 per cent humidity had a greenish overcast, whereas another body with the same varnish, at the same temperature but at a humidity of 45 deg, dried to exactly the same color as an air-dried job. I have cited these instances to show that the artificial drying of an enamel or varnish requires engineering skill.

CONCLUSION

In conclusion I wish to state that the paint maker and the paint engineer have co-operated whole-heartedly with the automobile and equipment engineers, and to meet the requirements of the various installations I have discussed has been no easy undertaking. It has meant the developing of enamels and varnishes of entirely different characteristics especially as regards their physical properties. The accomplishing of this has been of very material benefit in placing the paint and varnish industry on a more scientific basis.

Detroit, Mich.

Practical Applications of Electrometric Control

Dr. Paul E. Klopsteg, addressing a recent meeting of the Chicago Section of the American Chemical Society, cited the increasing number of important industrial applications for electrometric methods of measurement and control. This is particularly true in the case of hydrogen-ion determinations, the value of which has been recognized in scores of industrial processes. In the sugar industry, for example, one of the serious problems is the clarification of the raw juice before evaporation is started. This is accomplished by adding lime water to the juice and careful neutralization with CO_2 or SO_2 . The hydrogen-electrode method has been successfully used in controlling this process. In the sirup and sugar industry, two other problems have been successfully solved with the hydrogen electrode. One of them was the determination of acidity caused by fermentation in molasses and sirups. In this instance an indicator is of little use, because of the color and opacity of the sirup. In the preparation of glucose from starch, the neutralization of the acid with which the starch is digested can be satisfactorily controlled electrometrically.

The acidity of plant and fruit juices, both as regards actual acidity and total available acidity, is easily measured by similar methods. Work of this sort has been done by some of the large canning companies which are also studying the effect of fruit juices upon the cans, using the hydrogen electrode in their investigations.

The Bureau of Standards some years ago investigated the effect of H-ion concentration upon deposits obtained in metal plating baths and demonstrated the importance of this factor. In addition to these applications Dr. Klopsteg referred to problems in a number of other industries, of which the following is a partial list:

In the baking industry, fermentation takes place only within certain limits of p_H and there is an optimum value of acidity.

In filtration problems, especially of gelatinous material, there is a particular hydrogen-ion concentration at which the volume occupied by the material is a minimum. The same considerations apply to some problems of gelatin manufacture.

In the leather industry, the actual acidity in the various tanning processes is the controlling factor affecting practically all of the important properties of the finished leather.

Much of the recent progress in the manufacture of dentifrices has come about through the discovery that the actual acidity of toothpaste is an important factor in determining the effect of the paste on the teeth.

In the textile industry, hydrogen-electrode control has been exercised for wool-scouring liquors, in cloth finishing, and in the application of dyes.

Alsatian Potash Mines Returned to France

The Colmar Court of Appeal has delivered a judgment in the case of the Alsatian potash mines by which they are definitely returned to France. A business man, M. Koch, bought certain mining rights from the German company just before the mines were sequestered by the French Government. Later M. Koch claimed only 0.6 per cent of the rights he had acquired, but the tribunal of Mulhouse awarded M. Koch the whole area. The French Government appealed and the Colmar Court of Appeal awarded M. Koch 0.6 per cent of the mines and returned the remainder to France.

Radium Production in America—II*

Electroscopic Analysis of Radium-Bearing Products—Preparation of Standard Samples Used in the Standardization of the Electroscopes—Description of the Apparatus and Methods of Operation

By H. D. d'AGUIAR

THE electroscopic laboratory is of primary importance in a radium production plant. Without accurate determinations from this laboratory the work in the plant can never be anything but guesswork; whereas when it is functioning properly the progress of the work at each stage is accurately known. In a laboratory, such as this, where determinations of radioactivity are constantly being made, it is imperative that all samples of active matter be kept sealed in order to prevent possible radioactive contamination by the escape or spilling of radioactive material. The presence in the laboratory of highly active samples such as the sulphates and carbonates resulting from the different stages of the extraction process and samples from the crystallizing laboratory, or tubes of radium, will vitiate the measurements made.

All the chemical and manipulative work on the various samples received should be performed in a portion of the laboratory separate from that where the measurements are made, so that any accident causing the escape of emanation or the spilling of radium-bearing material shall not cause the contamination of the laboratory. While the errors of measurement caused by the escape of emanation are largely temporary, the continual escape of emanation will result in the walls becoming active due to the products of slow decay derived from the emanation.

It will be necessary so to plan the work of the laboratory that the determination of radium content of ores, sand tails and similar materials, by means of the alpha electroscope, will not be taking place at a time when tubed radium for estimation by gamma ray is present in the laboratory. Neither can tubed radium be present when readings are being made with the emanation electroscopes used for determining the strength of carbonates, sulphates or the samples of dissolved crystals and mother liquors.

ALPHA RAY DETERMINATIONS

The apparatus for these determinations is a small electroscope provided with a scale and a microscope by which the rate of fall of the leaf can be timed. One electrode extends through the case, terminating in an insulated handle, while the other passes through the amber insulation at the bottom of the head into a metal chamber below the head. This chamber is provided with a door permitting the samples to be measured to be introduced and removed easily. The container for the samples is made by providing a circular disk of metal about $\frac{1}{16}$ in. thick having a circular opening in the center about $\frac{3}{4}$ or 1 in. in diameter, with a metal tray into which the disk fits firmly, thus forming a space for the samples of a fixed area. This container

can be readily taken apart for cleaning after each determination. As the alpha rays have no penetration, even a cigarette paper stopping their passage, the principal point to be observed is that a definite area of the sample and standard be exposed, and not that a definite weight be used.

The electroscope may be charged with batteries or by a static charge generated with an ebonite rod or amber. Charging with a battery, however, is always preferable. A battery of about 300 v. potential will be required. The metal casting of the electroscope is grounded, as is one pole of the battery, while the other is attached to the charging arm of the electroscope. Upon turning this against the leaf holder and switching on the current, the leaf system will be charged. When so charged the fall of the leaf is watched through the microscope and the time required for it to fall a definite number of divisions on the scale is recorded with a stop watch. A record is made of the time in seconds and of the number of divisions. From these figures the number of divisions which the leaf will fall is calculated and recorded as the natural leak of the instrument in divisions per hour.

METHOD OF OPERATION

The standard ore, on which the amount of uranium has been determined by chemical analysis, is placed in the sample holder, carefully leveled and all particles removed from the surrounding metal by means of a small piece of cotton. The holder is handled as little as possible, only the edges being touched with the fingers. The sample prepared, it is placed in the chamber of the electroscope and the door closed. The electroscope is then charged and the time required for the leaf to fall through the same space as was selected for the determination of the natural leaf is taken. The standard is then removed, the holder cleaned and freed from any trace of ore by wiping with small bits of cotton. The sample of the unknown ore which is to be analyzed is then placed in the holder in the same manner. It is placed in the electroscope and the time taken for the leaf to pass through the same divisions as were selected for the standard is recorded. The same holder must be used for the three readings. Example:

Time required for the leaf to fall 10 divisions on the scale = 480 seconds.

$480 \div 10 = 48$ seconds per division.

3,600 seconds in 1 hour; divided by 48 = 75 divisions per hour = natural leak of the instrument used.

With the standard (say 3 per cent uranium oxide) the time required for leaf to fall 10 divisions = 120 seconds.

$(3,600 \times 10) \div 120 = 300 - 75$ (natural leak) = 225 divisions per hour.

With the unknown sample the time required for leaf to fall 10 divisions = 100 seconds.

$(3,600 \times 10) \div 100 = 360 - 75$ (natural leak) = 285 divisions per hour.

Therefore: $225 : 285 :: 3 : x$; and $x = 3.52$ per cent.

*For Part I see CHEM. & MET. ENG., vol. 25 No. 18, 1921, p. 825

The radium-uranium ratio in unaltered ores being a constant and 8 lb. of uranium oxide being equivalent to 1 mg. of radium, it is necessary only to know the total weight of the ore analyzed to compute the radium content in milligrams.

The control analysis on the sand tails is made in the same manner. The sample of the tails as received at the laboratory is dried over night (or until dry) in a drying oven at 105 deg. C. The sample is then ground in an agate mortar, if necessary, to reduce it to about the same grain size as the standard used. The determination is then made immediately and the results are reported to the plant for guidance in the dissolving work.

DETERMINATIONS BY EMANATION METHODS

The determination of radioactivity by the emanation method is used for samples of sulphates, carbonates, dissolved crystals and mother liquors.

The electroscope used for emanation determinations consists of the usual electroscope head mounted on an air-tight container, of about 10 liters capacity, provided with adjustable legs for leveling, a circular spirit level being mounted on the top of the head. The container is fitted with two gas-tight stop-cocks located on opposite sides of the container. One is placed near the top and the other near the bottom of the container. The head screws on and the joint is gas tight. The electrode extends through the amber insulation at the bottom of the head and is long enough to reach nearly to the bottom of the container. It is preferable to have the bottom of the container removable to facilitate cleaning should the electroscope become contaminated.

STANDARDIZATION

Before determinations can be made it is necessary to standardize the electroscope by means of emanation from a known quantity of radium. A small tube of radium containing about 1 mg., which is in equilibrium and has been carefully estimated by gamma comparisons with a standard tube, is opened and dissolved carefully in sulphate-free water containing about 1 per cent barium chloride and hydrochloric acid. This solution is then made up to volume in a 1-liter volumetric flask with dilute acidified barium chloride water and constitutes the standard stock solution. A quantity of this stock solution equivalent to about 1 microgram of radium is accurately pipetted off and diluted to 1 liter with acidified barium chloride water in a second volumetric flask. Several portions (one for each electroscope to be standardized) are pipetted off and transferred to tall aspirating bottles of about 250-c.c. capacity. The portions pipetted should be equivalent to about 40 millimicrograms of radium. The radium solution in the aspirating bottles is then diluted to about 100 c.c. with dilute acidified barium chloride water. The bottles are marked with the exact amount of radium they contain. These are the standardizing solutions. Each standard is then de-emanated by attaching it to an air pump. The air passing through the radium solution is drawn from outdoors and the air and emanation drawn off and passing through the pump are also passed outdoors by an outlet pipe through the wall. By so aspirating vigorously for 20 minutes all the emanation is removed. The intake-cock is then closed and the pump permitted to create a strong vacuum in the bottle. When this is done, the outlet stop-cock is closed and the exact time noted and recorded on the bottle.

Each bottle is treated in the same way. The bottles are permitted to stand for at least 3 days and 20 hours before being used for standardizing. The radium comes into equilibrium with the emanation in 30 days, the half period being 3.85 days—that is, one-half the total emanation is formed in 3 days and 20 hours. Therefore, knowing the exact time at which the radium was totally de-emanated and the time at which the emanation is again separated from the radium and transferred to the electroscope for standardization or measurement purposes, the fraction formed in the elapsed period of time can be definitely calculated from tables prepared by actual determinations throughout a period of 30 days. The accompanying table gives the constants of growth and decay which are used in calculating the amount of emanation formed for any intermediate period.

GROWTH AND DECAY OF RADIUM EMANATION

T = time. X = fraction of emanation remaining after time, T . Y = fraction of equilibrium amount formed in time T .

T	X	Y	T	X	Y
0	1.0000	0.0000	5 days	0.4066	0.593
1 hr.	0.9925	0.0075	6 days	0.3396	0.660
2 hrs.	0.9851	0.0149	7 days	0.2837	0.716
3 hrs.	0.9777	0.0223	8 days	0.2369	0.763
4 hrs.	0.9704	0.0296	9 days	0.1979	0.802
5 hrs.	0.9632	0.0368	10 days	0.1653	0.834
6 hrs.	0.9560	0.0440	11 days	0.1381	0.861
7 hrs.	0.9489	0.0511	12 days	0.1153	0.884
8 hrs.	0.9418	0.0582	13 days	0.0963	0.903

11 hrs.	0.9208	0.0792	16 days	0.0561	0.943
12 hrs.	0.9139	0.0861	17 days	0.0469	0.953
13 hrs.	0.9071	0.0929	18 days	0.0392	0.960
14 hrs.	0.9003	0.0997	19 days	0.0327	0.967
15 hrs.	0.8936	0.1064	20 days	0.0273	0.972
16 hrs.	0.8869	0.1131	21 days	0.0228	0.977
17 hrs.	0.8803	0.1197	22 days	0.0191	0.980
18 hrs.	0.8737	0.1263	23 days	0.0159	0.984
19 hrs.	0.8672	0.1328	24 days	0.0133	0.986
20 hrs.	0.8607	0.1393	25 days	0.0111	0.988
21 hrs.	0.8543	0.1457	26 days	0.0093	0.990
22 hrs.	0.8479	0.1521	27 days	0.0078	0.992
23 hrs.	0.8416	0.1584	28 days	0.0065	0.993
1 day	0.8353	0.1647	29 days	0.0054	0.994
2 days	0.6977	0.3023	30 days	0.0045	0.995
3 days	0.5827	0.4173	40 days	0.0007	0.999
4 days	0.4868	0.5132	50 days	0.0001	0.999

Example: If the emanation formed by the standards, or by any sample, is transferred to the electroscope 3 days and 20 hours after sealing, the fraction of the equilibrium amount of emanation formed will be:

Value of X for time t (3 days) = 0.5827.
Value of X for time T (20 hours) = 0.8607.
Therefore $X = 0.5827 \times 0.8607 = 0.5015$.

Standardizations are never made with standards which have not reached the half period, and it is even preferable to use standards which are in equilibrium.

METHOD OF OPERATION

About 1 hour before the time at which it is desired to transfer the emanation from the standard to the electroscope the apparatus is thoroughly de-emanated by drawing air from outdoors through the container of the electroscope by means of the air pump. The container is kept under a slight vacuum by opening the inlet tap only half way, while the outlet to the pump is opened fully. After 10 minutes the pump is cut off and when air has passed in sufficient amount to bring the pressure in the container to normal the inlet tap is closed. The electroscope is then charged, either with the battery or with the ebonite rod, and the natural leak of the instrument is determined by timing the fall of the leaf over the full scale and recording the value obtained in divisions per hour. The pump is then turned on and the outlet tap of the electroscope is opened. The inlet tap remains closed, thus creating a strong vacuum in the container. The vacuum is carried as far as is possible with the pump at hand. A manometer is attached to the inlet tap and the same vacuum is applied for every determination. When evacuated, the taps are closed, the pump and manometer are detached, and the

delivery tube of a drying bottle containing dry calcium chloride is attached to the inlet tap. The other tube of the drying bottle, which reaches to the bottom of the bottle, is attached to the delivery tube of the sample bottle containing the standard. The other tube of the standard bottle, which dips into the liquid, is attached to the pipe delivering air from outdoors. The stop-cock of the delivery tube of the standard bottle is opened and inlet tap of the electroscope container is partly opened. When the two vacuums balance the air inlet stop-cock on the standard bottle is slightly opened, thus permitting the vacuum to be filled and drawing the emanation from the standard bottle into the electroscope container. When the vacuum is filled, as shown by the ceasing of the bubbles at the end of the tube of the standard bottle which dips into the liquid, the inlet tap of the electroscope is immediately closed. The electroscope containing the emanation is then allowed to stand for 3 hours. At the end of this time it is charged and the time required for the leaf to fall is taken with a stop watch and recorded. This done, the electroscope is immediately attached to the air pump and the emanation removed by drawing air from outside through it exactly as was done previous to taking the natural leak. The drying bottle is also de-emanated in the same way. The drying bottle should be refilled with fresh calcium chloride after using two or three times. The standard is again de-emanated and sealed and put aside for future standardizations. The electroscope should be restandardized regularly once a month. The standards can be used over and over providing none of the liquid splashes beyond the stop-cocks during transfer of the emanation to the electroscope.

The time required for the leaf to fall is converted into divisions per hour and the divisions per hour of the natural leak are subtracted. Thus the following facts are obtained for each electroscope: (a) Natural leak in divisions per hour. (b) Millimicrograms in standard used. (c) Divisions per hour for standard.

Where the standard used is not in equilibrium, the divisions per hour for the standard are recorded as being produced by the fractional equivalent of emanation formed in the time which the standard has stood since de-emanation and sealing. Thus if the standard contains 40 millimicrograms of radium and has stood 3 days and 20 hours since sealing, when the emanation formed is transferred to the electroscope, because in that time one-half the equilibrium amount of emanation will be formed, the divisions per hour for the standard are recorded as having been produced by 20 millimicrograms of radium in equilibrium.

PREPARATION OF SULPHATE SAMPLES FOR ANALYSIS BY THE EMANATION METHOD

The samples of sulphates as received at the laboratory are sent to the section of the laboratory where the chemical work is done. Here they are first dried in an oven at 105 deg. C. The dried sample is ground finely in an agate mortar. One gram is then accurately weighed and ground together with 3 g. of a mixture containing 20 per cent ammonium chloride, 30 per cent barium chloride and 50 per cent lampblack. This mixture is transferred to a small iron crucible. The last traces of the mixture are removed from the mortar by means of a small bit of tissue paper and added to the mixture in the crucible. It is then covered with an iron lid, placed in a muffle furnace and roasted at a temperature of 1,050 deg. C. for 1½ hours. The crucible

is removed and cooled. It is carefully opened and the contents removed to a small beaker containing dilute hydrochloric acid and barium chloride. The crucible is carefully washed out with dilute acidified barium chloride water and the washings are added to the main solution in the beaker. The solution is then diluted to about 50 c.c., carefully boiled for 10 minutes, and filtered into a tall 250-c.c. sample bottle. The residue of carbon on the filter paper is washed with dilute acidified barium chloride water. The residue on the paper is then mixed with another 3 g. of the lampblack mixture and the roasting repeated. This is to insure the complete reduction of all sulphates to sulphides. The mixture when cool is dissolved in dilute acid barium chloride water, filtered and added to the main solution in the sample bottle. The solution should now measure about 100 c.c. The ground-glass stopper carrying the closure cocks and aspirating tube is then carefully inserted and the sample de-emanated by aspirating as were the standards. Fifteen minutes of aspiration is sufficient. The air inlet tap is then closed and the pump allowed to create a vacuum in the bottle. When this is done, the tap is closed and the time noted.

ANALYSIS OF SULPHATE AND CARBONATE SAMPLES BY THE EMANATION METHOD

Each sulphate sample bottle when de-emanated and sealed is delivered to the section of the laboratory having charge of the electroscopic work. They are allowed to stand for 3 or 4 days before estimation. When ready for estimation, the natural leak of the electroscope is taken and the emanation from the sample transferred to the container of the electroscope in the same manner as the emanation from the standards. The emanation is allowed to stand in the electroscope chamber for 3 hours. The leaf is then charged and the time of fall recorded with a stop watch. The calculation of the results is made in the following manner:

From the standardization it is known that

Time of fall of the leaf for 20 millimicrograms = 300 divisions per hour.

The natural leak of the instrument = 75 divisions per hour.

Therefore the rate of fall due to the standard = 225 divisions per hour.

Time of fall for natural leak taken just before introducing the sample = 8 minutes, which = 75 divisions per hour.

Time of fall for sample = 60 seconds.

So 60 seconds = 600 divisions per hour minus the natural leak of 75 divisions per hour = 525 divisions per hour for the sample.

Therefore $225 : 525 :: 20 : x$

$x = 46$ millimicrograms.

As the sample has stood (for example) 3 days and 20 hours, the factor as determined from the table is 0.50.

$46 \div 0.50 = 92$ millimicrograms of radium per gram of sulphates.

Or, $(454 \times 92) \times 1,000,000 = 0.0417$ mg. of radium per lb. of sulphates.

The electroscopic laboratory is usually furnished with the total weight of sulphates and the percentage of moisture which they contain by the analytical laboratory, so that the calculation of the number of milligrams in the entire lot is easily made from these figures.

The samples of carbonates as received at the laboratory are sent to the chemical section of the laboratory, where they are first dried at a temperature of 105 deg. C. The dried material is then thoroughly mixed. A 1-g. sample is then weighed off and dissolved in dilute hydrochloric acid containing barium chloride. The solution is boiled carefully, cooled somewhat and then filtered into a tall 250-c.c. sample bottle. If the sample

does not dissolve to a perfectly clear solution, the residue, which will consist mainly of unconverted sulphates, is incinerated in a small iron crucible, mixed with 3 g. of the lampblack reduction mixture, reduced in the muffle furnace and prepared for estimation exactly as described under the procedure for sulphates. In such cases there will be two samples for each determination, one representing the soluble portion of carbonate, and the other the insoluble portion or sulphate present. The samples so prepared are allowed to stand for 3 to 4 days. The emanation formed is then transferred to the electroscope and estimated just as was done with the sulphate samples.

The radioactivity is figured in the same way. The milligrams of radium found in the carbonate portion of the sample plus those in the insoluble or sulphate portion give the total activity of the material.

The insoluble portion is an index of the completeness of the carbonation process and should always be very small when the work has been properly carried out.

OTHER ANALYSES

The samples of the gelatinous silica press cakes submitted for analysis are prepared for analysis by the chemical section of the laboratory in the same manner as the samples of sulphates. It will usually be necessary to take a 2-g. sample for analysis.

The samples of dissolved crystals will be received at the laboratory marked with the volume of the sample and the volume of the liquid which each sample represents. The samples in 200- to 250-c.c. capacity volumetric flasks are prepared for determination by the chemical section of the laboratory. The operator preparing the sample will have to judge what fraction of 1 c.c. of the original sample or how many c.c. to pipette off for analysis and base his judgment on the usual radium content of the different fractions of dissolved crystals with which he is dealing and so proportion his samples that they will represent 60 millimicrograms or so as a maximum. This amount of the sample which has been made to definite volume is then pipetted into a sample bottle and made up to about 100 c.c. with dilute acidified barium chloride water. This sample is then de-emanated, sealed and delivered to the electroscopic section for estimation after standing 3 or 4 days. The results are computed to milligrams per c.c. and the amount present in the total volume of liquor is also reported.

Samples of the mother liquors from the different fractions in the crystallizing laboratory will be received stating the volume of the mother liquor which they represent. These are prepared for estimation by the chemical section in the same manner as the samples of dissolved crystals. As they are weaker in radium content, a correspondingly larger sample will be taken for analysis. The samples are then de-emanated, sealed and sent to the electroscopic section, where they are estimated after standing for 3 to 4 days.

All volumetric flasks, beakers, sample bottles and other containers used for containing the samples in any of the chemical manipulations are invariably washed thoroughly with water and then with dilute acidified barium chloride water before using. This is to insure freedom from any sulphate. Any water containing sulphates in solution would immediately vitiate the results by precipitating radium-barium sulphate. A stock solution containing 15 per cent barium chloride and 15 per cent concentrated hydrochloric acid is kept on hand

and about 100 c.c. per liter of this solution is added to all the water used in preparing samples for analysis. Under no circumstances should an untreated distilled water be used.

GAMMA RAY DETERMINATIONS

The electroscope used for gamma ray determinations is a small electroscope provided with a microscope and is similar to the one used for alpha ray determinations except that it has no chamber for holding samples. The electroscope is mounted on a long board provided with a metal track. A sample holder is made which slides along the track so that it may be set and held at a fixed distance from the electroscope by means of a lock nut. The varying of the distance is necessary, as the samples examined will be of widely different strengths, and samples of high radioactivity will have to be set at a longer distance from the electroscope so that the fall of the leaf will not be too rapid to time accurately. A large lead screen about $\frac{1}{4}$ in. thick is mounted between the electroscope and the sample holder to cut off all alpha and beta rays.

The determinations are made in the following manner: The tubes of radium will be received at the laboratory marked with their number indicating the fraction from the crystallizing laboratory which they represent and which will also be an indication of their probable radium content, and with the time at which they were tubed and sealed. The tube to be estimated is kept in a lead container made for the purpose and located in another room at some distance from the electroscope. The natural leak of the instrument is then taken by charging the leaf with the battery or an ebonite rod and timing the fall over the whole scale or over half the scale. The result is recorded in divisions per hour. A standard tube of radium is then laid on the sample holder and the time required for the leaf to fall over the same portion of the scale as was selected for the determination of the natural leak is recorded with the stop watch. The standard tube is then removed and replaced in the container where tubes under estimation are kept and the tube to be estimated is placed in the sample holder, being careful not to change its distance from the electroscope. The rate of fall for the unknown tube is then determined in the same manner and over the same portion of the scale. This done the time is noted and the tube is returned to the container. The calculation is then made as follows:

Natural leak for 10 divisions on the scale = 480 seconds = 75 divisions per hour.

Standard tube (10 mg.) requires 120 seconds = 300 - 75 (natural leak) = 225 divisions per hour for the standard.

Unknown tube requires 40 seconds = 900 - 75 (natural leak) = 825 divisions per hour.

Therefore $10 : 225 :: x : 825$ and $x = 32.2$ mg.

When the tubes estimated are not in equilibrium, the result so obtained is divided by the factor equivalent to the age of the tube reckoned from the time of tubing to the time of making the reading. Thus if 3 days and 20 hours has elapsed from the time the tube was sealed until the time it was read, the factor will be 0.50 and the number of milligrams as found in the above example are divided by this factor. Thus $32.2 \div 0.50 = 64.4$ mg. of radium in equilibrium.

The final readings are made on the tubes when they have reached equilibrium. They are then ready for such disposal as the producing company may wish to make of them.

New York City.

Electric Smelting of Iron Ore

BY FRANK HODSON

President Electric Furnace Construction Co., Philadelphia

A STATEMENT was made at a recent meeting of the officers of the American Mining Congress in Washington by Charles W. Potts, mine operator, of Bearwood, Minn., that "Present known reserves of high-grade iron ore, based upon constantly expanding requirements of the steel industry, will be exhausted in twenty years, and the merchantable grades of iron from the great mines of Minnesota will be, at the present rate of depletion, practically exhausted within the next fifteen years unless new discoveries are made."

The tremendous significance of this rapid depletion of native high-grade iron ore has not yet been fully realized, but a glance at the capital invested in iron and steel and kindred industries and its importance nationally will make anyone see the gravity of the situation. As in the olden days the possessors of metals ruled the world, so today control of iron is inseparably linked with world leadership. If, as Mr. Potts states, our available high-grade iron ore will be depleted in twenty years, is there also not a grave danger of our position today in the world's markets passing, unless the vast deposits of iron sands and low-grade ores in this country are properly exploited? Other countries—China, Japan, Brazil, India—with cheap labor, have immense deposits of iron ore. They have water power available and already are installing large smelting furnaces operated electrically for reducing the iron ores.

COMMERCIAL FEASIBILITY OF ELECTRIC SMELTING OF LOW-GRADE IRON ORE

The electric smelting furnace—using cheap water-generated power—will very probably in the next few years open up a vast supply of iron ore at present considered almost worthless. Immense deposits of iron sands and low-grade ores occur in the Atiron-dacks, on the Pacific Coast and in many other parts of the country. These ores are at present useless, as they cannot be economically treated in the ordinary standard blast furnace. Most of these deposits are in places where power is, or could be generated very cheaply; the ore can be concentrated and smelted into iron by specially designed electric furnaces.

The one thing essential after the financial backing is obtained is the selection of the right type of equipment for the work. Many previous attempts to smelt these ores electrically have failed, owing to wrong or no proper technical advice. A recent issue of *The Foundry* stated there are no less than seventy so-called "direct" processes for making steel direct from ore. Some of these are feasible under certain conditions, but they should not be attempted except on advice from disinterested metallurgists who have had practical electric smelting experience. These "direct" and "secret" processes to give steel direct from ore are the snag that has sunk many promising ventures.

There are several known and proved processes for electric iron smelting, chief of which is the Swedish Electrometall process. Already twenty-seven large installations, with a total capacity of 100,000 kw., are running or under construction in various parts of the world. This type of electric smelter uses the gases generated in the melting zone to preheat and partly

reduce the charge; it does not attempt to make steel direct, but in several cases the product is being tapped out into metal mixers or open hearth furnaces and from there into finishing electric furnaces. Dr. Stangfield in his report on the commercial feasibility of electric smelting of iron ores in British Columbia, writes:

"In Sweden the Electrometall type of electric smelting furnace has proved very satisfactory for the production of low-silicon pig iron. This is, as far as I am aware, the only type of electric furnace that has ever attained commercial success in the production of pig iron from ores. If a permanent smelting plant were being erected, the Swedish type of furnace would be selected."

Considerable publicity has been given recently to what was termed a recent Japanese discovery that iron sand and low-grade ores could be smelted and made into steel. There is nothing new in this invention; as long ago as 1907 John T. Jones, of Iron Mountain, Mich., had devised a similar process for treating low-grade ores. H. A. Greaves and H. Etchells, English scientists and inventors of the successful "Greaves-Etchells" electric steel furnace, also brought out a process a few years ago, in which black iron sand was passed down a rotating tube or kiln and from there to a finishing electric furnace. The ore in this tube is preheated and partly reduced by the gases given off in the electric furnace, and finished steel from sand and has repeatedly been made by their process.

A French inventor, Monsieur Basset, uses a similar method, but in his case external or additional heat is applied to the ore proceeding through the preliminary tube.

ADVANTAGES OF ELECTRICALLY MADE PIG IRON

As long as high-grade ore is available and coke reasonable in price, these electric processes of ore reduction cannot hope to compete with the standard blast furnace in anything but charcoal iron—or iron of special analysis. With the falling off in available supplies of high-grade ore and the generation of cheap electric power from water power, the electric smelters will come into their own. They can undoubtedly make iron superior in quality to that made in the standard blast furnaces. Very thorough tests made in Sweden and England with this electrically made pig iron also proved that by its use in the open-hearth furnaces considerable time could be saved in the steel-making operations. Actual figures have not been published, but in a number of cases that came directly under the writer's notice the saving in time per heat of steel was between 1½ and 3½ hours.

Although, therefore, the initial cost of electric pig iron may still be somewhat higher than ordinary blast-furnace pig iron, yet considerations such as that mentioned above and the extreme purity of the electric iron do not make the difference in first cost as large as would at first appear.

The electric smelter can also economically handle a very large proportion of turnings, borings and cheap scrap in its charge—material that is not suitable except in small proportions in the standard blast furnace.

In places like the Pacific Coast, where good ore is available near cheap, water-generated electric power and where at present most of the coke, pig iron or

steel has to carry heavy freights from the East, there is a splendid opening for someone with vision ahead to put down electric smelters and steel plant.

COMMERCIAL FEASIBILITY OF ELECTRICALLY MADE STEEL

Probably the future method of making even cheap steels will be to take hot blast-furnace metal, either from electric or standard blast furnaces, directly into a large metal mixer where additions of ore, cheap borings and turnings could be added, from there to a bessemer converter, where the metal would be given a partial blow only, and the deoxidizing and finishing off would be done very quickly in a series of electric furnaces.

In the process outlined there would be practically no loss of heat in the whole operation, the addition of ore and cheap scrap in the form of borings, etc., in the mixer would cause a thermic reaction and generation of heat, the bessemer operation would add more heat, and all that the electric furnace would have to do would be to deoxidize, adjust temperature and, where necessary, refine or make additions of alloys. The writer is confident this process would make the cheapest steel in the world.

Ceramics as a Byproduct of Coal Mining in Sweden

BY J. W. BECKMAN

AT A recent meeting of the Chemical Society of Sweden C. Crouquist showed that Sweden has a very ancient coal industry as well as a well-established clay industry. In Skane, the southernmost province of Sweden, coal has been mined ever since the fifteenth century. In those early days the coal was brought out for domestic use only, and from small seams, and it was not until 200 years later that active commercial mining operations took place. The coal veins that had been mined were very thin and the larger mining operations forced the abandoning of the early workings, finding wider veins. These were discovered at Höganäs, which place has since developed into a large industrial center.

The coal is of a more recent formation than that occurring in England and Germany and is found at depths from 10 to 100 m. The thickness of the coal seams vary from 30 to 60 cm. In between the coal seams there are clays and carboniferous slates. These clays have to be mined simultaneously with the coal to make it economical and feasible to bring it out.

The ash content of the coal varies from 5 to 50 per cent and more. It is free from sulphur and phosphorus and has all the characteristics of "sub-bituminous" coal. The railroads and industries of Sweden use the best qualities, although they are also used to some extent for domestic heating. The low grades are used as a source of energy at Höganäs and for the burning of clay products.

The clay-products manufacture is now the main operation at Höganäs. The clay, originally a waste product, has become of prime importance, and the quality of the products produced from it has become famous not only in Sweden but in many other countries. Firebricks, paving bricks, common building bricks, chemical ware, acid-proof bricks, terra cotta products, sewer pipes, sanitary ware and household articles are all being made. These products are pro-

duced in a simple way. The carbonaceous shales are piled in the open and set on fire. They burn completely, leaving a dense well-burned chamotte which is very desirable for the manufacture of pressed brick and other clay products.

The company operating the works at Höganäs also operates an electric furnace plant at Trollhättan, where alundum and carborundum are produced, and these products are used here as elsewhere in the manufacture of highly refractory bricks. Electrodes are also a product of this plant, their manufacture being virtually a ceramic industry, though utilizing different raw materials.

The accumulation of a large quantity of low-grade coal prompted one of the engineers of the Höganäs company to experiment for the purpose of finding a use for this material. He worked out a simple process for the reduction of iron ore at a low temperature by means of these inferior coals, producing a very pure iron sponge, well adapted, on account of its purity, to the manufacture of high-grade steels.

At the present time about 7,000 kw. is generated at the mine from low-grade coals. This energy is used by the industry itself and is also supplied to the adjacent countryside, and this power plant acts as a standby for one of the hydro-electric companies.

The total annual capacity of the plant is 450,000 tons of coal, 200,000 tons of clay, 150,000 tons of firebrick, 400,000 tons of sewer pipes, 7,000 tons of electrodes, 12,000 tons of iron sponge, as well as considerable quantities of other products.

Beckman & Linden Engineering Corporation,
San Francisco, Cal.

Switzerland as a Market for American Goods

American manufacturers and exporters are overlooking an important field for business development in Switzerland, says American Trade Commissioner H. Lawrence Groves in a special survey of the markets of that country published recently by the Bureau of Foreign and Domestic Commerce of the Department of Commerce.

In his report published as a convenient handbook of Switzerland, the Trade Commissioner calls special attention to the increased importance of that country as a financial and a commercial center. He says that Switzerland, located in the heart of Europe, is essentially an industrial nation, almost entirely lacking in raw materials. Consequently, its many industries are dependent on foreign countries for supplies of raw materials as well as for many semi-manufactured and finished products. In his opinion, supplying these commodities is of sufficient importance to merit much more intensive consideration than heretofore accorded on the part of our exporters.

The report is devoted to Switzerland exclusively. It reviews the country's industries, finances, natural resources, markets, etc. Conspicuous facts in its foreign trade are mentioned specifically. There is also information about advertising, credit and transportation agencies, and other similar trade factors.

The complete report is known as Special Agents Series 210—"Switzerland—A Commercial and Industrial Handbook." Copies can be purchased at 40c. each, from the Superintendent of Documents, Government Printing Office, Washington, D. C., and from the district and co-operative offices of the Bureau of Foreign and Domestic Commerce.

ENAMELED STEEL PLANT OF PFAUDLER CO., ROCHESTER, N. Y.

Enameled Steel Manufacture

Development of Glass-Lined Steel Containers—French Plate Glass First Employed—Enamel and Industrial Application Research Involved—Fabricating and Finishing the Steel—Mixing and Firing the Enamel—Erection and Auxiliary Departments

BY CHESTER H. JONES

THE origin of the glass-lined tank or sheet steel enameled container may properly be traced to the need for large containers in the brewing industry, where many sanitation difficulties were encountered in the preparation and storage of malt liquors. At the time the Pfaudler Co. decided to manufacture enameled tanks for this purpose there was no idea of producing the present-day complicated constructions such as steam-jacketed kettles, vacuum pans, etc. These have come as a development from the time when all enamels on containers of any size were applied to cast iron.

Preparatory to undertaking the manufacture of large brewery tanks a comprehensive investigation was carried out. Enamelers were consulted and it was found that the formulas extant were simply the product of rule-of-thumb experiments. These formulas reposed in the memories of individual enamelers rather than in written scientific data. One well-known class of enamel was made originally by taking ordinary rock chips from a granite quarry, grinding them to a powder and fusing to the metal to produce granite ware. Other methods were quite as crude, making conditions difficult for the manufacture of vessels of any size.

The first attempt was made with a cast-iron tank which went into a specially built furnace in 1887. At the end of the heat the door was opened, revealing a melted mass of cast iron. With this failure and since all formulas purchased from so-called scientific enamelers had failed, the company made a radical departure from the accepted methods and started to experiment with sheet steel.

In the process of this research French plate glass was first used as a basic enamel material. The plate was imported from France, broken up, the fragments ground to a fine powder and fused to the steel vessel. This was fairly successful and marked the origin of the glass-lined tank. The high cost of the imported plate caused the company to turn to the purchase of French bottle glass from the leading perfume manufacturers in the United States. This method was employed in the actual manufacture of glass-lined tanks for about fifteen years, during which time experiments to find other methods were continued and the organization was developed. Real scientific handling of the problem from the standpoint of the present state of the art began in 1908, and since that time the methods have been developed to the most modern stage of production. Research in the truly advanced interpretation still continues.

RESEARCH LABORATORY

The first building in evidence on entering the plant of the Pfaudler Co., at Rochester, N. Y., houses the research and control laboratory and is shown in Fig. 1. The work involved here requires a staff of ceramists, chemists and metallurgists, for the metal to be enameled must be studied in relation to the metallurgical properties which affect the ceramic properties of the coating, and the chemist must discover the chemical values best suited to the use of both. The building contains all the departments of this work, including chemical laboratory; balance room equipped, besides the balances, with a Thwing instrument for determining the expansion co-

FIG. 1. VIEW OF RESEARCH LABORATORY

efficient of glass; photographic dark room, and micro-metallographic laboratory.

The furnace room for testing is equipped with a two-crucible furnace for studies in enamel composition, and a large semi-muffle furnace. Here is also a drier for the pebbles. All of these are heated with gas fuel with draft furnished by low-pressure air. The grinding room is equipped with large and small pebble mills and is adjacent to a well-stocked enamel-compounding room. The welding experimental laboratory has, with other apparatus, an electric-welding outfit, made by the General Electric Co. The latest development here is the furnishing of an industrial application room for studying the application of enameled ware in relation to the materials in the many industries where it goes to make up the process equipment.

FABRICATING THE STEEL

The first step in the production of enameled steel is the shaping of the vessel from the steel sheet. The raw material arrives at the factory in flat rectangular or circular steel sheets varying in thickness from $\frac{3}{4}$ in. to $\frac{1}{4}$ in. or less. The dished heads for tanks are formed from the circular sheets on three hydraulic presses after previous heating in a coal-fired reverberatory furnace. Views of these pieces are shown in Figs. 2 and 3. Fig. 2 is a partial view of the steel layout room, while Fig. 3 is one of the stock rooms with the above-mentioned hydraulic presses showing in the background. Two overhead traveling cranes run the length of the fabricating department.

Bending rolls of various sizes are employed to form the circles for large vats from the flat plate. Some of these pieces appear in the left foreground of Fig. 2. The ends are welded to form a complete ring after rolling. Bevel shears cut bevels on the two edges for welding.

FIG. 2. VIEW OF STEEL LAYOUT ROOM

The welding department is furnished with twenty-four oxyacetylene welding stations and sixteen one-man electric welding units. Each welding station is isolated by separating with hanging sheets of loose canvas which confine the sparks of hot metal to one locality and at the same time do not interfere with the moving about of large pieces along the floor. The top of each compartment is open, permitting access to traveling cranes.

The acetylene gas is manufactured in a separate building in four units. The generators feed to a common main for conveyance to the welding stations. The oxygen is purchased from the Linde Co., arriving in steel bottles. These are placed in the acetylene generator house and likewise connected to a common main for the welding station.

GRINDING AND FLANGING

After the welding the surplus metal at the joint is removed by grinding. Fig. 4 shows a movable emery wheel equipment for such work on the interior of tanks. Rings which make up the sides of large sectional tanks or in cases where the cover must be bolted or riveted

FIG. 3. STEEL STOCK ROOM

must next be run through the flanging machine, one of which appears on the left in Fig. 5. The equipment is made to special design of the Pfaudler Co. It will turn the cold metal to an angle of 90 deg. with the side, and flange one edge of a ring or both edges simultaneously.

Following this operation the rings are trued in a rotary shear. The flanges are subsequently punched on machines which pierce ten holes at one operation.

SAND BLASTING

Before the enamel coating is applied, it is essential that the steel surfaces be thoroughly cleaned. Fig. 6 shows the operation in one of the six large sand blast rooms. The blasting equipment consists of blowers, excess dust removers and sand-conveying and storage equipment.

The sand-blast treatment is sufficient, since it removes grease, rust, oxide and all other foreign matter. At the same time a fine surface is given to the steel for the enameling operation.

The enamel is prepared and applied by both the wet and the dry process. There are in general four different coatings used depending upon the service to which the ware is to be subjected. One is supplied for the

malt industry only; the dairy, soft drink and pharmaceutical trade use another type; the third enamel is designed to resist all and any degree of acidity, and finally a special coat is used which is more decorative and while not compounded to combat acid has a reasonable resistance to it.

Raw materials ordinarily used are ground sand, quartz, feldspar, borax, cryolite, fluorspar, sodium and potassium compounds, and clay. The method of melting French plate glass onto the steel sheet has long been abandoned and the constituents which go to make up a glass as mentioned above are made in the form of a powder. The required proportions of each for a definite enamel are mixed, smelted together, and ground wet in ball mills to form a slip which may be applied to the steel surface with spraying machines.

The basis of all enamels is SiO_2 , which is obtained in the ground sand, quartz or feldspar. Borax or anhydrous boric acid (B_2O_3), like silica, is an essential

FIG. 5. FLANGING MACHINE

this operation a flocculating agent such as magnesium sulphate, clay or borax is added to increase the viscosity of the slip.

Ordinarily wet enamels are sprayed on the heavy pieces through the medium of a portable air spray nozzle guided by the hand of the operator. Chemical plant ware may be treated by the dry process, or dusting. In this case the metal surface is wetted and the dry powdered frit dusted on where it adheres to the water film. The dusting method has the decided advantage over the wet process in the production of acid-resisting wares, for no raw materials are added to the frit. These raw materials in an enamel lower the acid resistance, for while an enamel is a glassy coating it is not a solid glass and becomes less solid with the addition of raw materials which may not completely fuse with the frit during the brief operation of burning the enamel to the steel.

FURNACE ROOM

The equipment for burning enamel to the steel consists of a total of seven furnaces, four of which are the open type, two complete muffle type and one vertical furnace of special design used for firing small articles that would involve waste of heat if treated in the large furnaces. This furnace consumes oil for fuel, the remainder burning coke. Natural draft is obtained by high stacks. One of the larger furnaces with door raised appears in Fig. 7.

FIG. 6. SAND BLASTING

FIG. 4. GRINDING WELDED JOINTS

constituent of enamel with the possible exception of acid-proof enamels. Those enamels which contain no borax are much more difficult to apply to the metal. Cryolite functions in the mix as both a flux and an opacifier. Fluorspar is also an active flux. Barium carbonate of a pure grade produces finished coats of high luster and density, and gives the easy fusibility of lead without the poisoning feature attending the use of the latter. The action of zinc oxide is similar to that of barium carbonate. Sodium and potassium salts are active fluxes, the nitrate of soda being most frequently used.

The raw materials for making the frit are mixed by hand or in revolving drums. Thorough mixing by machinery is the more advisable, especially in making white enamels where the quality is inversely proportional to the length of time spent in obtaining a thorough melt. Fine grinding and mixing as accomplished by ball mills insure a uniform fusion product with the shortest time in the melting furnace. Five Abbé pebble mills and four special rotary smelters comprise the glaze room apparatus.

The enamel mixture is melted and fined in the smelting furnace until no lumps of unfused or undissolved material can be detected in the string of glass drawn from the melt. On cooling, the frit from the furnace is broken up and ground wet in pebble mills. During

Muffle furnaces are employed largely for burning light wares, especially the light enamels, while the heavier steel pieces are fired in the open type. The temperatures range from 1,500 to 2,000 deg. F. The temperature in any one firing depends on the enamel. Hoskins pyrometers record the temperatures of each furnace. The combustion chambers are constructed from silica brick, while the burning chamber is firebrick throughout. All doors are made up of firebrick blocks and steel and are operated by compressed air, as seen in Fig. 7.

ENAMEL APPLICATION ROOM

Adjacent to each battery of furnaces is one enamel application room. The coated ring or tank is picked up by a traveling charging crane and placed in the open-type furnace, where it is revolved on a turntable while burning. Two of these charging machines are operated by electric current, while others have air lift for the vertical movement and electric drive for the lateral operation. The muffle furnaces are served by power tongs, which pick the pieces from tables moving on industrial tracks along the front of the battery and place them within the burning chamber in each case. Pieces are also served to these tongs by an overhead electric crane paralleling the industrial track just mentioned. Part of one of the traveling tables is seen in the lower right in Fig. 7. The overhead crane is operated from a floor station near the furnaces.

The special upright circular kiln noted above is charged through split doors in the top and is equipped

FIG. 7. ENAMELING FURNACE

with two firing holes located in the side near the bottom. The waste gases from all furnaces is conducted through waste heat boilers in the power plant. The charging cranes were all designed by the company's engineers.

ERECTING DEPARTMENT

The burned wares next go to the erecting department, where assembly is made and packing accomplished in accordance with the customer's specifications. Fig. 8 shows a corner where tanks of certain sizes are built up. The department has six one-man electric welding stations which operate mainly in attaching the jackets to jacketed pans and tanks. One section is given over

FIG. 8. ASSEMBLY FLOOR

to detail assembly of sprays, motor and gear brackets, agitating mechanisms, etc. A portable electric welding station is operated in fastening the various details to the main body at this location. All surfaces are inspected and tested for enamel perfection and the mechanical devices are given operating trial before shipment.

POWER HOUSE

All the steam needed is furnished from three Wickes waste heat boilers. Two Worthington feed-water pumps and a Cochrane feed-water heater complete the boiler room equipment. Power is generated in one Nordberg engine connected to a Western Electric Co., 250-kw., 230-v., direct-current generator and one Westinghouse unit 200-kw., 230-v., direct-current machine. There are five Ingersoll-Rand steam-driven air compressors, three of which furnish air for the sand-blast plant and two supply air for operating furnace doors and tongs. A six-panel switchboard controls the electrical apparatus. All the power consumed in the plant is generated in this department.

AUXILIARY OPERATIONS

Other departments of the plant include a large machine shop, with planers, lathes and drill presses, which is supplemented by repair stations located throughout the various process departments; complete woodworking plant; stores department; hospital and first aid stations; painting shop for coating the unenameled portions of the apparatus; large-scale development of the laboratory department for research in applications to the industries, and finally the factory offices, engineering department and drafting rooms.

CONCLUSION

The plant is conveniently located for shipment of raw materials and products over the Erie Barge Canal, the New York Central, and Buffalo, Rochester & Pittsburgh railroads. It is well arranged for flow of process and ideally located for the health and morale of the working forces. The product is widely marketed to the food, pharmaceutical, dairy, beverage and other chemically-controlled industries.

The company through its research department has made a special study of these industries, with a view to meeting their requirements and developing the equipment accordingly.

Further continuous investigation must obtain to meet new needs in the rapid present-day development of scientifically operated industrial plant processes.

Firefoam Protection of Extra-Hazardous Risks in Manufactories

BY DUNCAN M. PATTERSON, M.E.

IN RECENT YEARS—that is, during the war—the fire protection interests have been confronted with many new forms of extra-hazardous risks, requiring other means of protection than water.

TYPICAL FIRE RISKS WHERE WATER PROTECTION IS INSUFFICIENT

Of these risks, the manufacture of dyes is perhaps the most prominent. Many of the coal-tar derivatives used in this industry are flammable liquids lighter than water. It is obvious that water would be useless for extinguishing fires started in such materials.

The paint industry is another business where the same peculiar hazards are encountered, while varnish manufacturing has even greater hazards than ordinary paints.

In varnish factories the gums and resins, together with the solvents used, are melted together in kettles over coal fires, and it is not uncommon for this to get so hot that the mixture boils over the sides and immediately ignites. In addition to this, the varnish is usually aged in large numbers of tanks 3 to 4 ft. in diameter, crowded together in floors of buildings, where a fire in one tank, caused either by a spark of static electricity igniting the fumes or from some external

FIG. 1. FOAMITE SPRINKLER HEAD

source, would set fire to the whole room, with the result that hundreds of gallons of burning varnish would be spread over the floor.

In the rubber business solvents are used to make the rubber cement and for preparing the "friction" holding the rubber lining of hose to the cotton jackets, so that in nearly every rubber plant there is one room containing quantities of carbon bisulphide or other solvents for rubber, making an extremely bad hazard.

In linoleum factories we have the oxidizing room, where the linseed oil is treated.

In furniture factories it is becoming the general practice to varnish by dipping the article repeatedly in vats of varnish and drying the piece between successive coats. This means that in such plants there is risk that the whole factory may be set afire, in which case the use of the ordinary water sprinkler could accomplish nothing.

Nearly all the manufacturers of automobiles today adopt this practice for enameling fenders and other parts of the bodies. The parts are hung on a slow moving endless chain. The parts when clean and dry dip down into a bath of enamels, then move on, the excess enamel draining off, and pass through a heated

oven, the source of heat being steam coils or electricity. This cycle is repeated several times before they are removed in the finished condition.

These vats of enamel are kept warm and, of course, the drying ovens are full of the fumes of the solvent being dried out of the enamel, so that a fire in one vat may ignite the whole series.

The above are merely a few of the most prominent hazards of the kind under discussion. It will be apparent that no matter how well a manufacturing plant may be otherwise protected against fire, such, for instance, as the well known automatic sprinkler system, hose stations, soda-and-acid extinguishers, the whole plant is menaced by these "powder magazines" in one part of the plant.

AUTOMATIC FIREFOAM SPRINKLER SYSTEM

Such risks must be protected by a medium which will exclude the air from the burning liquid in the manner which the well-known Firefoam system does in tanks of the large oil companies, and this is now possible by means of a special form of automatic Firefoam sprinkler system.

The system requires two solution tanks and two separate systems of piping, as the foam is produced by the reaction between an acid solution, aluminum sulphate, and a basic solution of sodium bicarbonate, to which the foaming ingredient known as Foamite is added. The reaction is:

The combination produces sodium sulphate, an inert salt, aluminum hydrate, a gelatinous material which stiffens the foam, and free carbon dioxide, which is held by the combined action of the gelatinous aluminum hydrate and the Foamite in the form of a mass of minute bubbles or foam.

This foam is projected on the burning object, completely covering it and excluding the air, while the bubbles, as they gradually break, liberate carbon dioxide, which inhibits combustion.

The foam produced is equal to eight times the combined volumes of the two solutions from which it was produced, so that 1 gal. of each solution will produce 16 gal. of fire-smothering foam. It will be seen that the foam is extremely light, having a specific gravity of approximately one-eighth that of water, and consequently is lighter than the lightest of coal-tar or petroleum products. It will, therefore, float on the surface of these, cutting off the air supply upon which the combustion depends, and will not sink down and float the liquids over the premises as will water.

The foam, being a mass of bubbles, should be created at the point when it is to be used; for, while quite tough and durable, it should be subjected to as little compression or agitation as possible, and it is not desirable to force the foam, after its creation, through lengths of pipe, around sharp corners or through small orifices.

SOLUTIONS MIXED AT SPRINKLER HEAD

The Foamite sprinkler head (Fig. 1), which is of the well-known Grinnell type, is therefore designed so that the two chemicals mix in the particular head or heads over the fire and are simultaneously released upon the fusing of the strut by the heat of the fire.

The two streams of chemical solutions then are thoroughly mixed by the peculiar construction of this head,

and the resulting foam showers down over the fire below.

The source of supply of solutions may be any variation of the standard approved sprinkler practice, such as gravity or pressure tanks, but there must be separate tanks and separate pipes, as the solutions must not mix except at the head.

Owing to the corrosive nature of the acid solution, the tank containing this must be either of wood of special construction, or of lead-lined steel.

For the same reason the Firefoam automatic sprinkler system is preferably of the dry pipe type, to avoid the expense of lead-lined pipe throughout for the acid line.

The usual practice is to use the dry pipe system and ordinary piping in the building, the only lead-lined pipe being that at the tanks in constant contact with the acid solution.

For the same reason the system should be thoroughly washed out after use with water, and, where possible, the basic solution is washed out through the acid line

FIG. 2. DIAGRAM OF VALVELESS SYSTEM

by means of a cross-connection at the end of each pair of lines, so the basic solution remaining in the basic line will be washed into the acid line and neutralize any of the acid solution which might remain in the latter after both had been drained back to their respective solution tanks.

The ordinary dry pipe valve, lead-lined up to the seat, may be used for the acid line, and the ordinary dry pipe valve for the basic line.

Installations of any size permitted by the fire insurance interests may be installed by using the accelerator valve in particularly large systems.

For small systems what is known as the valveless system may be used, which in its simplest form is shown in Fig. 2.

The solution tanks are filled two-thirds full of the chemical solutions, and air pressure built up to the pressure required to deliver the solutions to the heads.

The same pressure will also be built up in the pipe lines through the check valves, which have a small ori-

fice through them. This compensates for any minor leaks in the air piping, but the orifices are so small that they will not compensate when a sprinkler head is released. When this occurs, the unbalanced pressure in the solution tanks forces the solution up and out of the sprinkler heads.

There are a number of other methods which may be used in addition to those described, and a careful survey of the conditions with all the engineering data is required to devise the proper installation for any conditions. It will be seen, however, that this new application of Firefoam offers a means not only of reducing these extra-hazardous risks to a point where they are no greater than those of an ordinary fire, but also, by eliminating these special hazards, of reducing the risk on the whole plant, so that the lowest rate should be obtained on the latter.

Foreign Trade of Germany in 1920

The Federal Statistical Bureau of the German Ministry of Economics furnishes an itemized statement of Germany's foreign trade during the twelve months of 1920. The figures do not include reparations deliveries under the terms of the Treaty of Versailles.

The itemization of Germany's foreign trade for 1920, presented in the *Monatliche Nachweise*, is given in the accompanying table:

Articles	Imports, Double Centners*	Exports, Double Centners
Agricultural, animal, and vegetable products, including foodstuffs.....	65,625,129	14,095,778
Animal and vegetable spinning materials and manufactures thereof, including human hair, prepared feathers, fans, and hats.....	871,597	782,698
Brooms, brushes and sieves.....	2,602	24,829
